pelvis (pel′vis), *n.*; pl. *pelves* (-vēz). [NL., < L. *pelvis*, a basin, laver; cf. Gr. *πέλυξ*, *πελλίς*, *πέλλα*, a bowl: see *pelike*.] 1. A bony basin forming the most inferior or posterior one of the three great cavities—thoracic, abdominal, and pelvic—of the trunk of most terrestrial vertebrates. A perfect pelvis is formed on each side by the haunch-bones, consisting of ilium, ischium, and pubis, meeting in front at the pubic symphysis, and completed behind by the sacrum, with which the iliac bones articulate, and by more or fewer coccygeal or caudal vertebræ. But the pubic symphysis is often wanting in animals below mammals; there is sometimes an ischiac and often an iliac symphysis. In any case, a recognizable ilium or ischium or pubis, however rudimentary, constitutes in so far a pelvis. The human pelvis is complete, and

Human Pelvis, from the front.

1, crest of ilium; 2, base (uppermost) of sacrum; 3, symphysis pubis; 4, acetabulum or socket of thigh-bone; 5, iliac fossa, a part of the false pelvis; 6, ischium; 7, obturator foramen; 8, iliopectineal line, or brim of true pelvis. (Coccyx, not shown, directly behind pubic symphysis.)

of normal composition, but remarkable for its shortness, width, axial curvature, and obliquity with reference to the long axis of the body. A perpendicular to the plane of the inlet would leave the abdomen at the umbilicus, and a perpendicular to the plane of the outlet would strike the promontory of the sacrum. The pelvis is divided into *true* and *false*—the latter being that part which is above the iliopectineal line, the former below the same line, which thus represents, in part, the brim or superior strait of the true pelvis. The false pelvis is broad and shallow, composed, as far as bone is concerned, chiefly by the flaring iliac fossæ, its front wall being made by the lower part of the abdominal parietes; and in the erect attitude the mass of abdominal viscera rests largely upon this part of the basin. The true pelvis is more contracted, and chiefly bony as to its walls. Its inlet or superior plane, cordiform in shape, is circumscribed by the pelvic brim, which is formed by the iliopectineal crest, completed in front by the spine and crest of the pubes, and behind by the curved ridge and promontory of the sacrum. The lower plane, or outlet, known also as the inferior strait, is bounded by a very irregular line of bone, the point of the coccyx being

Pelvis of Horse (sacrum and coccyx removed), leaving the bones representing the "quarter," viewed from left side and behind. 1, crest of ilium; 2, surface for articulation with sacrum (not shown) to complete the pelvis; 3, narrow part of ilium; 4, acetabulum for hip-joint; 5, a small part of right pubis; 6, ischium.

in the middle line behind, and the tuberosity of the ischium on each side; between which three points the bony outlet is deeply emarginated behind, on each side, by the great sacrosciatic notch, and in front by the arch of the pubes, formed by the conjoined rami of the pubes and ischia. In life these notches are largely filled in by ligaments (the greater and lesser sacrosciatic ligaments on each side, and the triangular or infrapubic ligament in front). The obturator membrane also closes in what would otherwise be a large vacuity on each side, the obturator foramen. The inlet of the pelvis is not closed by any structure; but the outlet is floored by the levator ani muscle, the skin of the perineum, and associated soft parts. The pelvic cavity contains the lower bowel and most of the organs of generation. After puberty the male and female pelves differ usually to a recognizable extent in size and shape; that of the male being more massive and contracted, that of the female lighter and more expansive. See also cuts under *Catarrhina, Dromæus, Elephantinæ, Equidæ, innominatum, ligament, Ornithoscelida, ox, quarter,* and *sacrarium*.

3. [*cap.*] A genus of mollusks.—**Brim of the (true) pelvis**, the periphery of the pelvic inlet, separating the false from the true pelvis. It is now made of beef, especially for use in arctic expeditions, being an easily preserved food, which keeps for a long time and contains the largest amount of nutriment in the smallest space. 2. A quill, as of a goose or other large bird, cut to a point and split at the nib, used for writing; now, by extension, any instrument (usually of steel, gold, or other metal) of similar form, used for writing by means of a fluid ink.

Various forms of Pens.

1, quill pen, in which *a* is the feather, *b* the body, and *c* the nib; 2, steel pen and penholder, *a* being the handle, *b* a ferrule fitted to *a* and having a clamping socket into which the pen *c* is inserted and there held by pressure; 3 and 4, fountain-pens: the body of the handle *a* is a hollow reservoir for ink, *b* is the pen-holding device, and *c* and *d* are metal rods passing through small holes into the ink-reservoir, along which the ink flows by capillary action to keep the pen *e* supplied.

Pens of steel or gold have almost superseded the old quill pens. Pens are also manufactured to some extent of other metallic substances, such as silver, platinum, and aluminium bronze. Gold pens are usually tipped with a native alloy of osmium and iridium. They possess the advantage of being incorrodible by ink, besides having a fine, quill-like flexibility, and are exceedingly durable.

See cut under *calamary*.—**Electric pen**, a kind of autographic pen invented by Edison, consisting of a small perforating apparatus actuated by an electromagnetic motor in connection with a battery, and used in the manner of a lead-pencil. 3. *Eccles.*, sorrow for sin shown by outward acts under authority and regulation of the church; contrition manifested by confession and satisfaction and entitling to absolution; hence, absolution ensuing upon contrition and confession with satisfaction or purpose of satisfaction. Absolution has been given on these terms since primitive times in the church, and this ancient institution was afterward formally recognized as a sacrament by the Roman Catholic, the Greek, and other churches. The sacrament of penance includes four parts: contrition, confession, satisfaction, and absolution. It is required that there should be a genuine and a supernatural contrition for the sin committed—that is, a sorrow produced by the influence of the Holy Spirit, coupled with a firm purpose of amendment; that the sin should be confessed fully and unreservedly to a priest; and that satisfaction be made for it by a voluntary submission to such penalty or discipline as the priest may require and by restitution to persons wronged; and absolution can be granted only on these conditions. It can be administered by no one who has not received priest's orders. Every member of the Roman Catholic Church is obliged at least once a year to confess to his parish priest and to do penance under his direction; he cannot partake of communion without previous absolution, but is not either before confession or during his penitential discipline regarded as under ecclesiastical censure, which is inflicted on the contumacious only.

4. The penalty or discipline imposed by the priest in the above sacrament.

See *scourge* and *flagellum*.—**To do penance.** (*a*) To repent: obsolete except in the Douay version of the Bible, and in the usage of the Roman Catholic Church.

the dome by two semicircular or ogival vaults, intersecting at right angles. Upon the pendentives is supported, in place of the upper part of the dome of which they are segments, an independent dome of which the diameter is equal to that of the absent upper part of the first dome, or sometimes a lantern or a tower. The true pendentive is characteristic of Byzantine architecture, and is still commonly used in the various Oriental architectures based upon the style of building of the Greek empire. In it was found the solution of the problem of covering a rectangular space with a vault of circular plan. The term *pendentive* is often extended, but incorrectly, to any architectural device occupying the position of a true pendentive, and designed to answer the same purpose, but constructed of courses laid in horizontal beds and projecting each one beyond that below, or of a succession of arches corbeled out, or in any other manner which will meet the case. No such device, however, can be a true pendentive, unless the structure is in both form and construction a segment of a dome.

pendulum (pen'dụ-lum), *n.* [NL., a pendulum, neut. of L. *pendulus*, hanging, hanging down: see *pendulous*. Cf. *pendule*, *pendle*[1].] 1. Anything that hangs down from a point of attachment and is free to swing.—2. In *mech.*, a body so suspended from a fixed point as to move to and fro by the alternate action of gravity and its acquired energy of motion. The time occupied by a single oscillation or swing is counted from the time of the descent of the pendulum from the highest point on one side till it attains the highest point on the opposite side. This time is called the *period of oscillation* of the pendulum. A *simple pendulum* in the mechanical sense is a material particle suspended by a weightless rod and moving without friction. A single weight attached by a string, etc., approximates to an ideal simple pendulum. The period of oscillation of a simple pendulum in vacuo is

Pendulum.

$$\pi \sqrt{\frac{l}{g}} \cdot (1 + \tfrac{1}{4} A^2 + \ldots),$$

where $\pi = 3.14159+$, g is the acceleration of gravity, l is the length of the pendulum, and A is the total arc of oscillation. The quantity in parentheses is not affected by the radical sign. It will be seen that, unless the arc is very large, the period is almost independent of its magnitude. A *compound pendulum* is any pendulum not simple. The same formula for the period applies, l being the square of the radius of gyration divided by the distance of the center of gravity from the axis of rotation. The common clock-pendulum usually consists of a rod of metal or wood, suspended so as to move freely about the point of suspension, and having a flat circular piece of brass or other heavy material, called a *bob*, attached to its lower end. The metal rod, however, is subject to variations in length in consequence of changes of temperature, and, as the accuracy of the pendulum considered as a regulating power depends upon its always maintaining the same length, various combinations of two different metals, as brass and steel, under the name of *compensation pendulums*, have been adopted in order to counteract the effects of changes of temperature. These take particular names, according to their forms and materials, as the *gridiron pendulum*, the *mercurial pendulum*, the *lever pendulum*, etc. The *gridiron pendulum* is composed of parallel rods of brass and steel, arranged in one plane, and so connected together that the different degrees of expansion of the different metals compensate each other and maintain the compound rod of fixed length. The *mercurial pendulum*, devised by Graham, consists of one rod with a vessel containing mercury at the lower end, so adjusted in quantity that, whatever alterations take place in the length of the pendulum, the center of oscillation remains the same, the mercury ascending when the rod descends, and vice versa. Another form of compensation or compensating pendulum employs a curved bar composed of iron and brass brazed together, which is attached to the rod in a horizontal position, the brass downward. The unequal expansion of the metals under a rise of temperature tends to lift the center of gravity of the bob, and thus to compensate for the simultaneous increase in length of the rod. The pendulum is of great importance as the regulating power of clocks. Our clocks are nothing more than pendulums with wheel-work attached to register the number of vibrations, and with a weight or spring having force enough to counteract retarding effects of friction and the resistance of the air. A *reversible pendulum* is a pendulum so arranged that it may be suspended from either of two axes on its length at unequal distances from its center of gravity, and so placed that in the two positions each becomes axis of suspension and axis of oscillation, so that the time of vibration shall be the same in both positions. Bessel's reversible pendulum is symmetrical in external figure with respect to the plane equidistant from the two axes. Such a pendulum eliminates the effect of the atmosphere. A pendulum which makes exactly one oscillation per second is called a *seconds pendulum* (also written *seconds' pendulum* and *second's pendulum*). The length of a pendulum is the length of the simple pendulum having the same period—that is, the distance between the point of suspension and the center of oscillation (see *center*[1]). In the latitude of New York, and at the level of the sea, the length of the seconds pendulum is 39.1 inches nearly. As the force of gravity diminishes toward the equator and increases toward the poles, the seconds pendulum is shorter in lower latitudes and longer in higher. Besides its use as a regulator in clocks, the pendulum is applied to determine the relative and absolute acceleration of gravity at different places, and in this way the figure of the earth.

3. A chandelier or lamp pendent from a ceiling.—4. A guard-ring of a watch and its attachment, by which the watch is attached to a chain.—**Axis of oscillation of a pendulum.** See *axis*[1].—**Ballistic pendulum.** See *ballistic*.—**Conical pendulum**, a pendulum not restricted to move in one plane, the center of gravity being only restricted to the surface of a sphere.—**Cycloidal pendulum**, a pendulum so constructed as to vibrate in the arc of a cycloid instead of a circular arc, like the common pendulum. The vibrations of such a pendulum are perfectly isochronous.—**Electric pendulum.** (*a*) See *electric*. (*b*) A pendulum that at some point of its path closes a circuit, this in turn either reporting the beats of the pendulum at distant stations for time-comparisons, or directly controlling a number of clocks. See *electric clock*, under *clock*[2].—**Foucault's pendulum**, a conical pendulum with a very long wire and a heavy bob, designed to exhibit the revolution of the earth. At the north pole, the plane of oscillation, really remaining fixed, would appear to rotate about the vertical once in twenty-four hours. At the equator there would be no such effect; and at other latitudes there should be a slower rotation. See *composition of rotations*, under *rotation*.—**Gyroscopic, hydrometric,** etc., **pendulum.** See the adjectives.—**Invariable pendulum**, a pendulum intended to be carried from station to station, and to be oscillated at each so as to determine the relative acceleration of gravity at those points. This method assumes that the pendulum is not bent nor its knife-edges altered in position or sharpness in the course of transportation. Hence it is called *invariable*, not as being incapable of change, but as being secured against change for a limited time.—**Long and short pendulum**, a pendulum for determining the absolute force of gravity, consisting of a bob suspended by a wire the length of which

can be varied by a measured amount.—**Pendulum ferry-boat,** a ferry-boat that is swung from bank to bank of a river by the force of the current, requiring but little labor to guide or propel it. Boats on this principle are made fast to an anchor or to moorings placed up-stream in the middle of the river.—**Pendulum governor,** in *mech.*, a governor consisting of two revolving pendulums, of equal length and weight, attached to a spindle, the spindle and the pendulums having a common axis of rotation, and the spindle being driven by the motion of the engine or machine to be controlled. The angular velocity of revolution of the pendulums bears a constant ratio to the velocity of the prime mover. The pendulum-rods or -arms are thus made to take and hold a definite angle with the axis of their revolution, so long as the speed of the prime mover remains constant. Increase of speed in the latter increases this angle, and decrease of speed diminishes it. The pendulum-arms are connected by links to a collar that slides on the spindle, and the motion of this collar is made to regulate a valve supplying steam or gas to an engine, a belt-shift that moves a belt on cone-pulleys, or mechanism controlling the partial opening or closing of a gate supplying water to a wheel, etc. The supply of power is thus varied according to requirements, and the variation in velocity is confined to narrow limits. See *governor*, 6.—**Pendulum press,** a punching-press in which the punch is driven into the die by a swinging pendulous lever usually having a ball or weight at the lower end, and actuated by the foot of the operator, while with his hands he holds the piece to be punched.—**Pendulum pump.** (*a*) A direct-acting donkey-pump in which the fly-wheel oscillates in a vertical plane. (*b*) A pump in which the reciprocating motion of the piston is controlled by a pendulum. (*c*) A pump the handle of which swings on either side of its center of suspension. *E. H. Knight.*—**Simple pendulum.** (*a*) See def. 2, above. (*b*) A pendulum consisting of a spherical bob suspended from a cord or wire.

Dan. *pingvin*, a penguin, = Russ. *pingvinŭ*, an auk, < E.): origin uncertain. According to one view < W. *pen gwen*, 'white head,' the name being given to the auk in ref. to the large white spot before the eye, and subsequently transferred to a penguin. According to another view, *penguin* or *pinguin* is a corruption (in some manner left unexplained) of E. dial. *penwing* or *pinwing*, the pinion or outer joint of the wing of a fowl (< *pen*[2], quill, + *wing*): this name being supposed to have been given orig. to the great auk (in allusion to its rudimentary wings) and afterward transferred to the penguins.] **1**†. The great auk, *Alca impennis:* the original sense.—**2.** Any species of the family *Spheniscidæ* or *Aptenodytidæ*. (See *Spheniscidæ* for technical characters.) Penguins are remarkably distinguished from all other birds by the reduction of the wings to mere flippers, covered with scaly feathers (see *Impennes*, *Squamipennes*), used for swimming under water, but unfit for flight. The feathers of the upper parts have also broad flattened shafts and slight webs, being thus like scales; the feet are webbed and four-toed, though the hind toe is very short; the tail is short and stiff; the general form is stout and ungainly. On land the birds stand nearly erect and waddle clumsily, but they are agile and graceful in the water. They feed on fish and other animal food, and congregate on shore to breed in penguineries of great extent. Penguins are confined to the southern hemisphere, especially about Cape Horn and the Cape of Good Hope, and islands in high southern latitudes, coming nearest the equator on the west coast of South America, as in the case of Humboldt's penguin of Peru. There are more than a dozen species, referable to three

leading types. Those of the genus *Aptenodytes* are the largest, standing about three feet high, and have a slender bill. The name *Patagonian penguin*, applied to these, covers two species or varieties—a larger, the emperor penguin, *A. forsteri* or *imperator*, and a smaller, *A. pennanti* or *rex*. (See *emperor*.) *Jackass-penguins*, so called from braying, are medium-sized or rather small, with stout bill, as *Spheniscus demersus* of South Africa and *S. magellanicus* of Patagonia. (See cut at *Spheniscus*.) None of the foregoing are crested; but the members of the genus *Eudyptes* (or *Catarractes*), as *E. chrysocome* or *chrysolophus*, known as *rock-hoppers* and *macaronis*, have curly yellow plumes on each side of the head. (See cut at *Eudyptes*.) Other medium-sized penguins are *Pygoscelis tæniata*, *P. antarctica*, *P. antipoda*, and *Dasyrhamphus adeliæ*. The smallest penguin, about a foot long, is *Eudyptila minor* of Australian and New Zealand shores. The largest, which was taller than a man usually is, is a fossil species named *Palæeudyptes antarcticus*, from the New Zealand Tertiary. —**Papuan penguin**, a misnomer of *Pygoscelis tæniata*, a penguin of the Falklands and some other islands, but not of Papua.

[= F. *penis* = Sp. *pene*, < L. *penis*, for orig. **pesnis*, tail, penis, = Gr. πέος for *πέσος, penis; akin to MHG. *visel*, G. *fisel*, penis.] The male organ of copulation; the intromittent or copulatory organ of the male sex of any animal. The penis in the vertebrates is generally, in part at least, homologous with the organ so named in man, but not in the invertebrates; it is sometimes double, as in certain reptiles, crabs, etc. In some invertebrates the term is extended to organs which deposit spermatozoa without being intromittent. Many of the older writers on entomology included under this term all the external male organs of generation, dividing them into the phallus, or true intromittent organ, and the forceps or claspers used in copulation. The corresponding organ of the female sex in mammals is termed the *clitoris*. See cuts under *Dendrocœla*, *Lepadidæ*, *Proteolepas*, *Alcippe*, *Balanus*, *Cestoidea*, and *Squillidæ*.

Certain Reptilia possess a pair of eversible copulatory organs situated in integumentary sacs, one on each side of the cloaca; but it does not appear in what manner these *penes* are morphologically related to those of the higher Vertebrata. *Huxley*, Anat. Vert., p. 99.

This view is not satisfactory; but the variations and irregularities in the forms indicate that the actual sense of the radical element was not known by the later users, and thus would go to support a foreign origin, and to favor the suggested etym. from *pand*, pawn, pledge: see *pawn*[1], *pane*[1].] **1†.** A silver coin weighing 22½ grains, or the 240th part of a Tower pound. 6. In composition, in the adjectives *fourpenny*, *sixpenny*, *eightpenny*, *tenpenny* (which now designate nails of certain sizes), originally (in the 15th century) noting the price of nails (fourpence, etc.) a hundred. The original significance of these adjectives—that of price—was lost in the actual fluctuation of prices, though the terms themselves survived. The dialectal pronunciations, *four-pun' nails*, *six-pun' nails*, etc., seem to have suggested the erroneous idea that *pound* and not *penny* was the original word in these phrases—familiar adjectives denoting the price of small purchases. See *nail*, 5.—**A penny for your thoughts,** I would give something to know what you are thinking about.

Peter's pence, an annual tax or tribute in several countries of northern Europe, consisting of a penny, formerly paid to the papal see at Rome. In England it is said to have originated under Offa of Mercia in the eighth century, and it was abolished by Henry VIII. The sums now sent to Rome under the name of Peter's pence are voluntary contributions by Roman Catholic people everywhere for the maintenance of the Pope. Also *Peter-pence*.

The old payment called *Peter-pence*, from the days of the Mercian King Offa, was originally made for maintaining an English college in Rome. Baronius and other Roman writers misrepresented this payment as a quitrent for the kingdom, and an acknowledgment of dependence on Rome. They have been sufficiently confuted by Spelman and Collier.

Opinions regarding the authorship of these books differ greatly. Some scholars believe that they, with the book of Joshua, were written substantially by Moses, Joshua, and their contemporaries; others hold that they were compiled at a much later period (in part about the seventh century B. The feast of Pentecost, while primarily connected with the celebration of the completion of harvest, by the offering of first fruits, etc., seems also to have been associated in the minds of the later Jews with the giving of the law on the fiftieth day after their departure from Egypt. It always precedes the Jewish New Year by 113 days.

2. The feast of Whitsunday, a festival of the Christian church, observed annually in remembrance of the descent of the Holy Ghost upon the apostles during the feast of Pentecost. Pentecost is the third of the great Christian festivals, the other two being Christmas and Easter. It is connected with its Jewish predecessor, not only historically (Acts ii. 1–11), but also intrinsically, because it is regarded as celebrating the first fruits of the Spirit, as the Jewish Pentecost celebrated the first fruits of the earth (Lev. xxiii. 17). In the primitive church the term *Pentecost* was used both for Whitsunday and for the whole period of fifty days ending with Whitsunday.

of the luminous body. The figures represent the so-called Hipparchan diagrams of a lunar and a solar eclipse. Any portion of the moon in penumbra appears slightly dimmed, the more so the nearer it is to the umbra. At a station of the earth in the moon's penumbra, the disk of the sun is partially hidden, forming a partial (or, possibly, an annular) eclipse.

If the source of light be a point, the shadow is sharply defined; if the source be a luminous surface, the perfect shadow is fringed by an imperfect shadow called a *penumbra.* *Tyndall*, Light and Elect., p. 13.

Swift, Panegyrick on the Dean.

=Syn. 3. *Parsimonious, Penurious, Miserly, Close, Niggardly, Stingy, Mean*, covetous, avaricious, illiberal, sordid, chary. The first seven words express the spirit or conduct of those who are slow to part with money or other valuable things. *Parsimonious* is perhaps the most general of these words, literally sparing to spend, but always careful and excessively sparing. *Penurious* means literally in penury, but always feeling and acting as though one were in poverty, saving beyond reason; the word is rather stronger than *parsimonious*, and has perhaps rather more reference to the treatment of others. One may be *parsimonious* or *penurious*, through habits formed in times of having little, without being really *miserly*. *Miserly*, feeling and acting like a miser, is generally applied to one who, having some wealth, clings to it for fear of poverty, or in provision for some possible exigency of the future, or especially for its own sake, as delighting in the mere possession of wealth. *Close* has the vigor of figurative use; it may be a shortening of *close-fisted*. *Niggardly* is the least limited to money, and has the most to do with others; it expresses a meanly parsimonious treatment of others, a neglectful, self-defeating, or stingy saving. *Stingy* expresses the most of opprobrium: as, Queen Elizabeth was called *frugal* by her friends, *stingy* by her enemies, and *parsimonious* by the rest of the world. It indicates a grudging, narrow-hearted or unreasonable parsimony in giving or providing. *Mean* shows a tendency toward emphasizing the idea of a close or narrow and mean-spirited handling of money. See *avarice*.

penuriously (pē-nū′ri-us-li), *adv.* In a penurious or parsimonious manner; with scanty supply.

The common peony is *P. officinalis*, an herb with large, commonly red flowers, one on a stalk, a native of southern Europe and central Asia. A kindred species, *P. tenuifolia*, of Siberia and parts of Europe, has the leaves finely cut, and hence is called *slender-leafed, fennel-leafed, fern-leafed*, or *fringed peony*. A second typical species is the tree-peony, *P. Moutan*, a taller shrubby species from Japan and China, with large rose-colored or nearly white flowers, several on a stalk. These and one or two other species furnish the numerous hybrid and other varieties of the gardens, which vary greatly in color and are often double. Originally, and most commonly down to the middle of the eighteenth century, cognition; thought and sense in general, whether the faculty, the operation of faculty, or the mental product. Most psychologists since Plato had made two departments of mental action, the orectic and the speculative; the latter was called *perception*, but it did not include belief founded on testimony. This use of the word is now uncommon in technical language.

2. The mental faculty or operation of gaining knowledge on the ground of a real action of an object upon the mind; also, the complex of sensations which form the vehicle of this knowledge. Regarded cognitively, perception includes all the knowledge that is acquired involuntarily without our being aware of any process, and which seems to be directly given by sense. Regarded as conscious content, it consists of a sense-complex, more or less modified and controlled by associated ideas.

Perception . . . being the first step and degree toward knowledge, and the inlet of all the materials of it.
Locke, Human Understanding, II. ix. 15.

Perception is most properly applied to the evidence we have of external objects by our senses.
Reid, Intellectual Powers, I. i.

Perception is that process by which the mind, after discriminating and identifying a sense-impression (simple or complex), supplements it by an accompaniment or escort of revived sensations, the whole aggregate of actual and revived sensations being solidified or "integrated" into the form of a percept—that is, an apparently immediate apprehension or cognition of an object now present in a particular locality or region of space.
J. Sully, Outlines of Psychol., p. 152.

The manner in which the constituent elements in a *perception* are combined differs materially from what is strictly to be called the association of ideas. To realize this difference we need only to observe first how the sight of a suit of polished armour, for example, instantly reinstates and steadily maintains all that we retain of former sensations of its hardness and smoothness and coldness, and then to observe how this same sight gradually calls up ideas now of tournaments, now of crusades, and so through all the changing imagery of romance.
J. Ward, Encyc. Brit., XX. 57.

3. An immediate judgment founded on previous experiences, more or less analogous to what takes place in vision; insight; mental purview. Thus, mathematical, esthetic, and moral judgments founded on long familiarity with imaginary or ideal objects are called *perceptions*.

It is admitted on all sides that the *perception* of an object necessarily implies the recognition of the object as this or that, as like certain objects, and as unlike certain other objects. Every act of *perception*, therefore, involves classification. *J. Fiske*, Cosmic Philos., II. 107.

Her physical organization, being at once delicate and healthy, gave her a *perception*, operating with almost the effect of a spiritual medium, that somebody was near at hand. *Hawthorne*, Seven Gables, vi.

A great method is always within the *perception* of many before it is within the grasp of one. *De Morgan.*

Perhaps the quality specially needed for drawing the right conclusion from the facts, when one has got them, is best called *perception*, delicacy of *perception*.

It. *pericarpio* = Pg. *pericarpo*, < NL. *pericarpium*, < Gr. περικάρπιον, a pod, husk, < περί, around, + καρπός, fruit.] In flowering plants, the seed-vessel or ripened ovary. It should accord in structure with the ovary from which it is derived, but extensive changes frequently take place during fructification by which the original ovarian form is obscured. Thus, by abortion the original number of cells in the ovary may be reduced in the fruit, as in the oak, chestnut, elm, and birch; or by the intrusion of false partitions the original number may be increased in the fruit, as in *Datura*, *Linum*, *Astragalus*, etc. The pericarp may acquire external accessions, as the wing of the maple, ash, and hoptree, the prickles on the pod of *Datura*, *Ricinus*, etc., or the barbs of the *Boraginaceæ*. Connected organs may modify the ovary, such as the adnate calyx of the apple, the pappus of the *Asteraceæ*, the persistent style of *Clematis*, the fleshy calyx of *Gaultheria*, or the fleshy receptacle of the strawberry. The walls of the ovary may change in consistence in the mature pericarp, being leaf-like in the pea-pod, columbine, caltha, etc., thickened and dry in nuts and capsules, fleshy or pulpy in berries, and fleshy without but indurated within, as in all stone-fruits. Where the walls of the pericarp are composed of dissimilar layers, the layers are distinguished as *exocarp*, *endocarp*, *epicarp*, *mesocarp*, and *putamen*. In cryptogams the pericarp is a variously modified structure containing certain organs of reproduction. Thus, in the *Characeæ* it incloses the oösperm, while in the *Floridæ* it incloses the carpospores. The term is also sometimes synonymous with the theca or capsule of mosses.

Petrographers are not wholly agreed in regard to the nomenclature of the varieties of peridotite. Among known varieties are the following: *dunite*, composed almost entirely of olivin, with a few grains of picotite, magnetite, or some other accessory mineral; *saxonite*, a variety consisting of olivin and enstatite; *lherzolite*, of olivin with enstatite and diallage; *buchnerite*, of olivin, enstatite, and augite; *cortlandite*, of olivin and hornblende; *picrite*, of olivin and augite. Of these varieties, the first four have been found in meteorites as well as in terrestrial rocks; the others, so far as known, are exclusively terrestrial. Olivin passes readily into serpentine; hence many olivin rocks are found more or less completely altered into that mineral, so that the distinction between olivin and serpentine rocks is one not easily preserved. Peridotite is known to be in some cases an eruptive rock, and is generally supposed to have been such in all cases. That most serpentine rocks are the result of the alteration of some peridotic material is also generally conceded; that serpentine may have been produced in some other way has, however, been distinctly proved.

7. In *anc. pros.*, a group of two or more cola. According to the number of cola it contains, a period is dicolic, tricolic, tetracolic, etc. The end (apothesis) of a period must coincide with the end of a word, and is also characterized by admitting of syllaba anceps and hiatus. A single colon treated thus is also regarded as a period (a monocolic period). A monocolic, dicolic, etc., period is a meter. (See *meter*[2], 1 (*b*) (2).) Certain periods are known as *lines* or *verses*. (See *line*[2], 6 (*b*).) A group of periods is called a *system*.

4. In *rhet.*: (*a*) Of or pertaining to a period or complete sentence; complete in grammatical structure. (*b*) Noting that form of sentence in which the sense is incomplete or suspended until the end is reached.

These principles afford a simple and sufficient answer to the vexed question as to the value of the *periodic* sentence—or sentence in which the meaning is suspended till the end—as compared with the loose sentence, or sentence which could have been brought to a grammatical close at one or more points before the end.
A. S. Hill, Rhetoric, p. 152.

In the former, a periodic function is one whose operation being iterated a certain number of times restores the variable. Thus, $1 - x$ is such a function, since $1 - (1 - x) = x$. But in the theory of functions a periodic function is defined as a function having a period. For a more general definition, see *function*.—**Periodic inequality**, a disturbance in the motion of a planet dependent upon its position in its orbit relative to another planet, and hence going through its changes in periods not excessively long: opposed to *secular inequality*, which is a disturbance dependent upon the relative positions of two planetary orbits.—**Periodic law**, in *chem.*, a relation of chemical elements expressed by the statement that the properties of the elements are periodic functions of their atomic weights. If the chemical elements are arranged in the order of their atomic weights, at regular intervals of the series will be found elements which have similar chemical and physical properties—that is, there is a periodic recurrence of these properties. If the elements showing this periodic recurrence are arranged in order by themselves, they form a group which, having similar properties and relations, follows a regular progression in the individual differences of its members.—**Periodic stars.** See *star*.—**Periodic winds.** See *monsoon* and *trade-wind*.

Several periotic bones are found in nearly all vertebrates. They may all remain distinct throughout life, but they are usually more or less confluent with one another, and may be, as in man, completely fused; furthermore, they may ankylose with other cranial bones, and thus give rise to certain parts of the compound temporal bone. The parts of a skull called *mastoid* are commonly outgrowths of periotic bones. The set of periotic bones composes a bony case for the inner ear, much as the case of a watch covers the works, and this is termed the *otocrane, otic capsule,* or *skull of the ear.* When mastoid parts are superadded, the resulting bone is called *petromastoid.* The human periotic bones form what are called the *petrous* and *mastoid* sections of the temporal bone. It is used in piloting submarine boats, and consists substantially of a vertical tube with a lenticular total-reflection prism at the top, by which horizontal rays are projected downward through the tube, and brought to a focus, after which they are received by a lens the principal focus of which coincides with that point. The vertical cylindrical beam thus formed is converted into a horizontal one again by a mirror inclined at 45° from the vertical axis of the tube, and is thus conveyed to an eyepiece, through which, by turning the tube on its vertical axis with its attached prism, a view of all the supernatant objects around the vessel may be obtained. peritoneum, peritonæum (per″i-tō-nē'um), *n.* [= F. *péritoine* = Sp. *peritoneo* = Pg. It. *peritoneo,* < LL. *peritonæum, peritoneum,* < Gr. περιτόναιον, prop. neut. of περιτόναιος, stretched over (περιτόναιος ὑμήν or χιτών, the membrane inclosing the lower viscera), cf. περίτονος, stretched over, < περιτείνειν, stretch over or around, < περί, around, + τείνειν, stretch: see *tone.*] 1. The membrane lining the abdominal cavity and investing its viscera. It is a strong, uncolored, transparent, serous membrane, with a smooth, moist, shining surface, attached to the subjacent structures by the subperitoneal areolar tissue, and forming a closed sac, except in the female, where it is continuous with the mucous membrane of the Fallopian tubes, or oviducts. From the walls of the abdominal and pelvic cavities it is reflected at various places over the viscera, which it serves to invest and at the same time hold in position by its folds or duplicatures. These folds or duplicatures are of various kinds. Some of them, constituting the mesenteries (see *mesentery*), connect certain parts of the intestinal canal with the posterior abdominal walls; others form the so-called ligaments of the liver, spleen, stomach, and kidneys, the broad ligaments of the uterus, and the suspensory ligament of the bladder; still others form the omenta, folds attached to the greater and lesser curvatures of the stomach. That part which lines the abdominal and pelvic walls is called the *parietal* or *external* peritoneum; that which more or less completely invests the viscera, the *visceral* or *internal.* The cavity of the peritoneum is divided into two unequal parts by the constriction at Winslow's foramen; of these, the upper posterior one, lying back of and below the stomach and liver, is called the lesser cavity; the greater cavity lies in front and below. In vertebrates below mammals, in which there is no diaphragm, the peritoneum and the pleura (which is the corresponding thoracic serous membrane) are thrown into one, lining the whole pleuroperitoneal cavity and investing its contained viscera. The name *peritoneum* is extended to various similar or analogous, though not necessarily homologous, membranes or tunics which line the body-cavity of many different invertebrates.

Peritoneum of Human Female, in longitudinal section, somewhat diagrammatical.

2. In brachiopods, an investment of the alimentary canal, by which the latter is suspended in the perivisceral cavity as by a mesentery. Special folds form the gastroparietal and ileoparietal bands, respectively connecting the stomach and intestines with the parietes.

Permian (pėr'mi-an), *a.* and *n.* [< ML. **Permianus,* < *Permia,* Perm (see def. 1).] **I.** *a.* **1.** Relating to the city or government of Perm in eastern Russia.—**2.** Relating to the Permians.—**3.** An epithet applied by Murchison and his coadjutors in a geological reconnaissance of a part of Russia, in 1841, to a group of strata overlying the Carboniferous, and forming the uppermost division of the Paleozoic series. The rocks of which the Permian system is composed are largely red sandstone, and their equivalent in England had then been known as the *New Red Sandstone,* to distinguish it from the *Old Red Sandstone,* which lies beneath the Carboniferous. Eventually the New Red of England was found to be divisible (paleontologically) into two groups, of which the older was classed with the Paleozoic, and the newer placed in the Mesozoic. In Germany there is a well-marked division of the Permian into two lithologically distinct groups; hence it is sometimes designated as the *Dyas,* a name coined in imitation of *Trias.* The divisions of the Permian in Germany are a lower series of sandstones, red and mottled in color (hence the name *Pœcilitic* has been applied to them), called the *Rothliegendes,* and an upper series of dolomites, marls, limestones, etc., called the *Zechstein.* The flora of the Permian in general closely resembles that of the Carboniferous, and several of the most characteristic plants of the latter pass upward into the Permian, but rise no higher. The cycads appear first in the Permian, and are largely increased in number and importance in the Trias. The Permian fauna is, on the whole, less rich than those of the overlying and underlying groups. The Permian is of great economical importance in Europe, as the repository of extensive deposits of rock-salt, gypsum, and other saline combinations.

3. In *math.*, a linear arrangement of objects resulting from a change of their order. *Permutation* differs from *combination* in this, that in the latter there is no reference to the order in which the quantities are combined, whereas in the former this order is considered, and consequently the number of permutations always exceeds the number of combinations. If *n* represents the number of quantities, then the number of permutations that can be formed out of them, taking two by two together, is $n \times (n-1)$; taken three and three together, it is $n \times (n-1) \times (n-2)$; and so on. Sometimes called *alternation*. See *combination*, 5.

3. In *law*: (*a*) A limitation intended to be unalterable and of indefinite duration; a disposition of property which attempts to make it inalienable beyond certain limits fixed or conceived as being fixed by the general law. *Pollock.* The evils incident to rendering any specific piece of land or fund inalienable, and thus shutting it out from the general circulation of property, early led the courts to hold provisions for a perpetual suspension of the power of alienation to be void. The desire of owners of estates to perpetuate the wealth of the family led to attempts to create forfeitures and gifts over to other persons, by way of shielding the successor in the title from temptation to alienate; and as the right to create life-estates and trusts, and to add gifts over to other persons upon the termination of precedent estates, could not be wholly denied, the question has been what temporary suspension of the power of alienation is reasonable and allowable, and what is too remote and to be held void as "tending to create a perpetuity." (See *remoteness*.) The limit now generally established for this purpose in varying forms is substantially to the effect that no disposition of real property or creation of an estate therein is valid if it suspends the absolute power of alienation for more than a period measured by a life or lives in being plus 21 years and 9 months. Hence, since literal perpetuities are no longer known, except in the law of charities, etc., the phrase *rule against perpetuities* has come to mean in ordinary usage the rule against future estates which are void for remoteness as "tending to create a perpetuity." (*b*) Duration to all futurity; exemption from intermission or ceasing. —**4.** In the doctrine of annuities, the number of years in which the simple interest of any principal sum will amount to the same as the principal itself; or the number of years' purchase to be given for an annuity which is to continue forever; also, the annuity itself.—**In perpetuity**, for an endless or an indefinite length of time; forever.

★**persistence** (pėr-sis′tens), *n.* [Also *persistance;* < F. *persistance* = Sp. Pg. *persistencia* = It. *per-*

sistenza, < ML. **persistentia*, < L. *persisten(t-)s*, persistent: see *persistent*.] 1. The quality of being persistent; steady or firm adherence to or continuance in a state, course of action, or pursuit that has been entered upon; especially (of persons), a more or less obstinate perseverance, perseverance notwithstanding opposition, warning, remonstrance, etc.—2. The continuance of an effect after the cause which first gave rise to it is removed: as, the *persistence* of the impression of light on the retina after the luminous object is withdrawn; the *persistence* of force.—**Persistence of force**, the law of mechanics. The phrase was introduced by Herbert Spencer to sum up all the laws of mechanics, especially the two principles of the permanence of matter and the conservation of energy. The law of action and reaction may be considered as consisting in the persistence of the algebraic sum of the momenta; and in fact every such law may be stated in an integrated form which contains an arbitrary constant independent of the time.—**Persistence of vision**, the continuance of a visual impression upon the retina of the eye after the exciting cause is removed. The length of time varies with the intensity of the light and the excitability of the retina, and ordinarily is brief, though the duration may be for hours or even days. The after-image may be either positive or negative, the latter when the bright parts appear dark and the colored parts in their corresponding contrast-colors. It is because of this persistence that, for example, a firebrand moved very rapidly appears as a line or circle of light. The phenakistoscope, zoëtrope, and other similar contrivances depend for their effect upon this principle. = **Syn. 1**, *Industry*, *Application*, etc. (see *assiduity*), pertinacity, doggedness.

3. The art of representing solid objects on a flat surface so that when they are viewed the eye is affected in the same manner as it would be by viewing the objects themselves from a given point. By *perspective*, in common language, is meant *linear perspective*, or the art of delineating the outlines of objects, of their shadows, and of their reflections. The theory is that the positions of the delineated points in the picture are such that if rays, or straight lines, were drawn from the corresponding *original points* in the natural objects to the eye of the spectator, and if the picture were then interposed in the right position, it would be pierced by these rays at the *points of delineation*. It follows that perspective supposes that a picture is to be looked at with one eye placed in a particular position; and if it be otherwise looked at, the perspective necessarily appears false. This position of the eye, called the *station-*

Perspective.

JBCK, an original plane; *KCDL*, another original plane; *CK*, their intersection, an original line; *ABCD*, plane of delineation; *E*, station-point; *EFGH*, directing plane; *EADH*, vanishing plane of original plane *JBCK*; *BC*, its intersecting line; *AD*, its vanishing line; *FG*, its directing line; *EABF*, vanishing plane of original plane *KCDL*; *DC*, its intersecting line; *AB*, its vanishing line; *HG*, its directing line; *C*, intersecting point of line *CK*; *A*, its vanishing point; *G*, its directing point; *EG*, its director; *AC*, its delineation.

point, or *point of sight* (which phrase with old writers has, however, another meaning), is, according to the directions of most treatises, placed much too near the picture to represent the mean position of a person looking at it. Ar-

tists consequently find it necessary to modify the forms which strict perspective would prescribe. To ascertain how an *original line* or *plane* (that is, a line or plane in nature) is to be delineated, we have to consider, first, the *intersecting point* or *line*, also called the *intersection of the original line* or *plane* (that is, the point or line where the original line or plane, extended if necessary, cuts the *plane of delineation*, or the plane of the picture extended to infinity), and, second, the *vanishing point* of the original line, or the *vanishing line* of the original plane (that is, the point or line where the plane of delineation is cut by a line or plane passing through the eye parallel to the original line or plane). An original line is represented by some portion of the line from its intersecting point to its vanishing point; and every line in a given original plane has its intersecting point on the intersecting line and its vanishing point on the vanishing line of that plane. It is also proper to consider the *directing plane*, or plane through the eye parallel to the picture; the *directing line*, or line in which the directing plane cuts an original plane; the *directing point*, or point in which the directing plane is pierced by an original line; and the *director*, or line from the eye to a directing point. It is further necessary to take account of the *direct radial*, or *principal visual ray*, being the perpendicular let fall from the eye upon the plane of delineation; the *center of the picture*, or *center of vision* (called by old writers the *point of sight*), being the foot of that perpendicular; and the *principal distance*, or *distance of the picture*, being the perpendicular distance of the plane of delineation from the eye. The *ground-plane* is the level plane on which the spectator is supposed to stand. The *horizontal line*, or *horizon*, is the line in which the level plane through the eye cuts the picture, passing ordinarily through the center. This would better be termed the *horizontal line at infinity*, for, owing to the dip of the horizon (which see, under *dip*), it differs sensibly from the delineation of the true horizon. Linear perspective is merely a branch of descriptive geometry, itself an application of projective geometry. Perspective is intimately connected with the arts of design, and is particularly necessary in the art of painting, as without a correct observance of perspective no picture can have truth. Perspective is illustrated in the correct delineation of even the simplest positions of objects.

4. A drawing or representation in perspective; specifically, a painting so placed at the end of an alley, a garden, or the like, as to present the appearance of continuing it, and thus produce the impression of greater length or extent. Stage scenic painting is of this nature.

It is also called *plane of projection*, *plane of the picture*, *picture-plane*.—**Projected perspective,** a modification of ordinary perspective in which the picture is further from the eye than the original objects.

=Syn. *Opinion*, *Belief*, *Persuasion*, *Conviction*, and *Faith* agree in expressing the assent of the mind. *Opinion* has the least feeling or energy, is most intellectual. *Belief* may be purely intellectual, or largely moral by the consent of the feelings or the will. *Persuasion* is a word borrowed from the field of action; primarily, we *persuade* one to do something by motives addressed to his feelings or interests; when the word is applied to opinions, it seems to retain much of its original sense, suggesting that the *persuasion* is founded largely on the feelings or wishes: we have a *persuasion* of that which we are willing to believe. *Conviction* starts from the other side, primarily suggesting that one was rather reluctantly forced to believe by the weight of evidence; it is now more often used of settled, profound, and earnest beliefs: as, his deepest *convictions* of right and duty. *Faith* rests upon belief, but implies confidence in a person on whose authority one depends at least partly, and the gathering of feeling about the opinion held; it is a confident *belief:* as, to have implicit *faith* in a friend or a promise. See *inference*, and quotation from Wordsworth under definition 2.

4. In *astron.*, a deviation of the motion of a planet or comet from a fixed orbit or from its regular velocity in that orbit. Perturbations are caused by the gravitating action of bodies other than the primary or central body. They are commonly and conveniently conceived, not as drawing the planets out of their orbits, but as consisting in gradual changes of the elements of the orbits themselves. All perturbations due to gravitation are, strictly speaking, periodical. But some of them, which depend upon the relative situation of the orbits of different planets, go through their changes in such vast intervals of time that they are more conveniently regarded as progressive and not periodic, and are termed *secular perturbations;* while others, depending for the most part upon the relative situations of the planets in their orbits, go through their changes in comparatively short intervals of time, and can only be represented as periodic, and these are technically called the *periodic inequalities*. = **Syn.** 1. ★**perturbatory** (pėr-tėr'bā-tō-ri), *n.* [< *perturbate* + *-ory*.] A name once used by real and pretended believers in the divining-rod to indicate a hypothetical power assumed to reside in certain individuals whereby they can exert a perturbing influence upon the motion of a swinging pendulum, etc. Its characteristics were an expansive quality, residing most abundantly in the thumb and forefinger, whereby the center of gravity of a pendulum held by these digits would be caused to describe a circle, and a compressive quality, belonging to the middle finger, which resists such motion. A man with a high compressive or "active" perturbatory, touching with his middle finger the hand of another with the expansive perturbatory well developed in thumb and forefinger, might neutralize the perturbatory in the latter, which is of the "passive" variety. A person equally endowed with these perturbatories would be negative, and so forth.

The passive *perturbatory* is a high degree of expansive, and the active *perturbatory* in like manner a powerful compressive. *Jour. Franklin Inst.*, CXIX. 112.

As late as 1825 some old-fashioned people still wore perukes, and a reminiscence of them remains in Great Britain in the wigs of the Lord Chancellor, the Speaker of the House of Commons, judges, barristers, etc.

It is not used of a disobedient spirit toward civil law, and *perverse* is only indirectly so used. *Perverse* has reference to one's attitude, in both conduct and opinion. The *perverse* person is settled in habit and disposition of contrariness; he not only likes or dislikes, acts or refuses to act, by the rule of contradiction to the wishes, commands, or opinions of others, especially of those whom he ought to consider, but he is likely even to take pains to do or say that which he knows to be offensive or painful to them. *Perversity* may be found in a child, but it is so settled an element of character as to be rather the mark of an adult. Many of them are wont, like albatrosses, to follow ships for many days at sea, to feed upon the refuse of the cook's galley, and may sometimes be taken with hook and line. In powers of long-sustained flight they surpass all other birds, but, with the exception of one genus (*Pelecanoides* or *Halodroma*), they cannot dive. The descriptive systematic science of rocks. The terms *petrography, petrology,* and *lithology* were all originally used for the science of rocks without precise definition applicable under present conditions. Each has been used in a broad sense for the science of rocks as earth masses and, in narrower scope, for the study of small specimens in their minuter characters of composition and texture. With the development of the scientific study of rocks as to character, origin, and relationships, students have found it convenient to use one term for the science treating the detailed chemical, mineral, and textural characters of rocks as objects, classifying and naming them, while using another term for the study of the origin, relations, and occurrence. *Petrography* is used in a limited sense in America and England, and to some extent elsewhere. In Germany, however, it is applied to the broader science (petrology). *Lithology* has been used in the limited sense of 'petrography,' but has come to have a less technical meaning, referring to the general properties of stony materials. The tendency of recent times, in the definition of sciences dealing with rocks, is voiced in the Lexique Pétrographique of the International Congress of Geologists (1901), where *petrography* is defined as the descriptive science of rocks (lithology), and *petrology* as the scientific study of rocks.

Petrography, properly the descriptive part of the science of rocks for which the more general name is petrology or lithology, but *petrography* is widely used as a synonym of the latter.

Sw. *petroleum* (MD. *peterolie*), < ML. *petroleum* (also *petreleum, petrelæon,* < MGr. NGr. πετρέλαιον), rock-oil, < L. *petra* (< Gr. πέτρα), rock, + *oleum* (< Gr. ἔλαιον), oil: see *oil.* A ML. adj. *petroleus,* pertaining to rocks (neut. *petroleum,* or *oleum petroleum,* rock-oil), is given.] An oily substance of great economical importance, especially as a source of light, occurring naturally oozing from crevices in rocks, or floating on the surface of water, and also obtained in very large quantity in various parts of the world by boring into the rock; rock-oil. Petroleum was known to the Persians, Greeks, and Romans under the name of *naphtha;* the less liquid varieties were called ἄσφαλτος by the Greeks, and *bitumen* was with the Romans a generic name for all the naturally occurring hydrocarbons which are now included under the names of *asphaltum, maltha,* and *petroleum.* The last name was not in use in classic times. The existence of petroleum in Pennsylvania and New York has been known from almost the earliest time of the settlement of those States by Europeans, but it was not until 1859, when oil was obtained by boring at Titusville on Oil Creek, a branch of the Allegheny river, that it began to be of commercial importance. In 1911, in the United States, the production of crude petroleum, according to the office of the U. S. Geological Survey, exceeded two hundred and twenty million barrels, and the world's production each year is now nearly three hundred and fifty million barrels. The crude oil undergoes refining and is put upon the market in various forms (see *kerosene, naphtha, rhigolene,* etc.), but much the largest part of this product has the form of an oil suitable for burning in lamps in all parts of the world. Russia follows the United States in the amount of production. The region near Baku on the Caspian produced seventy-six million barrels (of forty-two gallons) in 1902, but declined to fifty-two millions in 1911. Productive Russian fields are being worked near Grosny, Maikop, etc. The exported petroleums of the United States are chiefly from rocks of Devonian age; those of Baku occur in the Tertiary. An important part of the transportation of the crude material in the United States is effected by pipes laid beneath the surface, through which the oil is forced. See *pipe-line.* Also called *coal-oil, earth-oil.*

They are small flues which distribute the heat round the still. The still bottom rests upon the fire-tiles, *r,* which cover the throttles and are laid in a circle. Phalangidea (fal-an-jid'ē-ạ), *n. pl.* [NL., < *Phalangium* + *-idea.*] An order of tracheate *Arachnida*. The segmented abdomen is not distinctly separate from the cephalothorax; the falces or cheliceres are two- or three-jointed; the pedipalps are five-jointed and filiform; the eyes are two (to eight?) in number; and the eight legs are generally very long and slender, sometimes excessively so, the whole body appearing of insignificant size in comparison with them. They are most nearly related to the mites or acarids, though more nearly resembling spiders in some respects. They have no spinnerets or poison-glands, and are perfectly harmless. Many of the longest-legged forms are known as *harvesters*, *harvestmen*, *harvest-spiders*, and *shepherd-spiders*, and in the United States as *daddy-long-legs*. The order is also called *Opiliones*. There are several families, including *Phalangiidæ*, *Gonyleptidæ*, *Trogulidæ*, and *Sironidæ*. Also *Phalangida*, *Phalangita*. The legs reach the maximum of length and attenuation in this family, being sometimes more than twenty times as long as the body. The eyes are close together on the top of the head; a very long penis can be protruded from beneath the mouth; the cheliceres are exposed, diversiform, well developed; and the pedipalps are moderately long. phalanx (fā′langks or fal′angks), *n.*; pl. *phalanges* (fā-lan′jēz) or (except in anatomy) *phalanxes* (fā′langk-sez or fal′angk-sez). [= F. *phalange* = Pg. *phalange* = Sp. It. *falange,* < L. *phalanx* (*phalang-*), < Gr. *φάλαγξ* (*φαλαγγ-*), a line or order of battle, a rank of soldiers, a phalanx (def. 1), also a round piece of wood, the bone between joints of the fingers and toes, etc.] 1. In *Gr. antiq.*, in general, the whole of the heavy-armed infantry of an army; particularly, a single grand division of that class of troops when formed in ranks and files close and deep, with their shields joined and long spears overlapping one another so as to present a firm and serried front to a foe. The celebrated Macedonian phalanx was normally drawn up sixteen ranks deep, the men being clad in armor, bearing shields, and armed with swords and with spears from 21 to 24 feet long. In array the shields formed a continuous bulwark, and the ranks were placed at such intervals that five spears which were borne pointed forward and upward protected every man in the front rank. The phalanx on smooth ground, and with its flanks and rear adequately protected, was practically invincible; but it was cumbrous and slow in movement, and if once broken could only with great difficulty be reformed.

> Anon they move
> In perfect *phalanx* to the Dorian mood
> Of flutes and soft recorders. *Milton,* P. L., i. 551.

2. Any body of troops or men formed in close array, or any combination of people distinguished for firmness and solidity of union.—3. In Fourier's plan for the reorganization of society, a group of persons, numbering about 1,800, living together and holding their property in common. See *Fourierism.*—4. In *anat.* and *zoöl.*: (*a*) A row or series of bones in the fingers or toes. Hence—(*b*) One of the bones of the fingers or toes; a digital internode, succeeding the metacarpal or metatarsal bones, collectively constituting the skeleton of the third and distal segment of the hand or foot: so called from their regular disposition in several rows. The common number of the phalanges of each digit is three, but lizards have respectively 4 and 5 on the second and third digits. This is only exceptionally increased, as in the flippers of some cetaceans and extinct reptiles; but it is frequently reduced, as in most of the digits of birds, and in the inner digits of mammals which have five fingers and toes. The term seems to have meant any one of the cross-rows of small bones between the successive knuckles of the fingers or toes, or the longitudinal series of small bones of any one finger or toe. But usage transfers the sense of *phalanx* to any one of these bones, two or more of which are *phalanges.* See cuts under *Artiodactyla, carpus, Catarrhina, foot, hand, Ichthyosauria, Perissodactyla, pinion, Plesiosaurus, solidungulate, tarsus,* and *Ornithoscelida.* (*c*) One of the fiddle-shaped cells of the lamina reticularis of the Cortian organ. Also called *Deiters's phalanges.*—5. In *zoöl.*, a group or series of animals, of indeterminate classificatory value; one of several groups which may be interposed above genera and below classes or orders. A phalanx frequently corresponds in value to a subfamily, but has no recognized fixed place in classification. Sometimes synonymous with *cohort* or *agmen.*—**Basilar phalanx,** a phalanx of the proximal row.—**Middle phalanx,** a phalanx of the middle row.—**Ungual phalanx,** the terminal phalanx, on which is the nail.

There are 3 species, usually placed in as many genera, of elegant and varied coloration, and in general resembling sandpipers; but the body is depressed rather than compressed, and the plumage of the under parts is thick and compact to resist water, upon which these little birds swim with great ease and grace. They are found on inland waters and along the coasts of most parts of the world, sometimes venturing far out to sea. The whole tendency is to the reduction in number of these slits in ascending the vertebrate scale, and to their impermanence in the development of the embryos of the higher vertebrates. In adult reptiles, birds, and mammals they have all disappeared, excepting the trace of the first one, which persists as the auditory passage. In batrachians their progressive loss is seen in the transition from gilled tadpoles to the adults with lungs. In fishes and lower vertebrates than fishes more or fewer persist as ordinary gill-slits or branchial apertures. Phasianus (fā-si-ā'nus), *n.* [NL., < L. *phasianus*, < Gr. *φασιανός*, a pheasant: see *pheasant.*]

Reeves's Pheasant (*Phasianus* or *Syrmaticus reevesi*).

The typical genus of the family *Phasianidæ* and subfamily *Phasianinæ*, formerly nearly conterminous with the family, now restricted to such forms as *Phasianus colchicus*, the common pheasant, long domesticated in Europe. They have a much-lengthened tail, with long acuminate middle feathers, and the head crestless but provided with lateral tufts. At least 16 species are commonly referred to this genus (in several sections, ranked by some authors as genera). One of the most remarkable is *P.* (*Syrmaticus*) *reevesi*, of northern China, in which the tail reaches the maximum length of 5 or 6 feet. The plumage is beautifully varied with black, white, chestnut, and golden yellow. *P.* (*Catreus*) *wallichi* is the cheer, or Wallich's pheasant, of the Himalayas, with a long, broad tail and much-varied plumage. *P.* (*Graphophasianus*) *soemmeringi* is Sömmering's pheasant, of Japan, with coppery-metallic plumage and very long tail. *P.* (*Calophasis*) *ellioti* is a gorgeously colored pheasant of the mountains near Ningpo, in China. Certain green-breasted pheasants, as *P. versicolor* of Japan and *P. elegans* of China, form a small group. Ring-necked pheasants, as *P. insignis* and *P. mongolicus*, have a white ring around the neck. The above-named approach more and more nearly to the ordinary pheasant as domesticated in Europe, of which the Turkestan *P. shawi* is a near relative. The silver and golden pheasants, though long-tailed, are now placed in other genera (*Euplocamus* and *Thaumalea*). See further under *pheasant*.

Phasmidæ (fas'mi-dē), *n. pl.* [NL. (Serville, 1831), < *Phasma* + *-idæ.*] A family of *Orthoptera*, typified by the genus *Phasma*, composing with the *Mantidæ* the series *Gressoria* or *Ambulatoria*. They are known as *specters*, *leaf-insects*, *walking-leaves*, *walking-sticks*, etc., from their extraordinary protective mimicry of the twigs and leaves upon which they live. The body is usually long and slender, and the wings, when not abortive, are foliaceous. A member of this family, *Diapheromera femorata*, is the common walking-stick of the northern and eastern United States. See cut under *Phasma*.

Phasmina (fas-mī'nä), *n. pl.* [NL., < *Phasma* + *-ina*[2].] A group of orthopterous insects corresponding to the family *Phasmidæ*.

(See the technical names.) (*a*) *Phasianus colchicus*, the bird originally called *pheasant* from its supposed origin, of which nothing is certainly known, and now for many centuries naturalized in Great Britain and in other parts of Europe. The cock bird in full plumage is nearly three feet long, of which length the tail is more than half. The head and neck are deep steel-blue, glancing greenish in some lights; and there is a bare red skin about the eyes. The general color is golden-brown, varying to chestnut or plain brown, on most parts intimately barred or laced with black. The

hen is more yellowish-brown, and only about two thirds as long. This pheasant runs into some varieties in domestication, and also crosses freely with several related species. The several other forms of the restricted genus are definitely known as to their origin and habitat, all being natives of China and Tibet and more southerly regions of Asia, as well as of Japan and many other islands included in the Oriental fauna. Several of these are often seen in aviaries and in semi-domestication. They are such as Shaw's, *P. shawi*; the Mongolian, *P. mongolicus*; the Yarkand, *P. insignis*; the Formosan, *P. formosanus*; the ring-necked, *P. torquatus*; the Chinese ringless, *P. decollatus*; the Japanese green, *P. versicolor*; the green-backed golden, *P. elegans*; also pheasants known as Reeves's, Wallich's, Sömmering's, Swinhoe's, Elliot's, etc. Pheasants have often been introduced in the United States, where, however, none have been thoroughly naturalized, except the cases of *P. versicolor* and *P. sœmmerringi* in Oregon and Washington. (*b*) Hence, any bird of the subfamily *Phasianinæ* or (with a few exceptions) of the family *Phasianidæ*. (*c*) In the United States, the ruffed grouse, *Bonasa umbella*: so called in the Southern and Middle States wherever the bobwhite (*Ortyx virginiana*) is known as the *partridge*, and called *partridge* in the Northern States wherever the bobwhite is known as the *quail*. Hence the phenix often serves as an emblem of immortality. Allusions to this myth are found in the hieroglyphic writings, and the fable survives in popular forms in Arabia, Persia, and India. By heralds the phenix is always represented in the midst of flames.

The greatness of the change is sufficiently hinted in the Vision of St. John: "I saw a new heaven and a new earth; for the first heaven and the first earth had passed away, and there was no more sea" (Rev. xxi. 1). In the matter of elementals, the new earth will be identical with the old; in the matter of *phenomenals,* the new earth will be different from the old. *Boardman,* Creative Week, p. 289.

His [Locke's] integrity is also illustrated in his acknowledgment of the unimaginable, and in this sense incognizable, in our thought of Substance. He tries to *phenomenalize* it; but he finds that it cannot be *phenomenalized,* and yet that we cannot dispense with it.
Encyc. Brit., XIV. 760.

How pitifull and ridiculous are the grounds upon which such men pretend to account for the lowest and commonest *phænomena* of nature without recurring to a God and Providence! *South,* Sermons, IV. ix.

The term appearance is used to denote not only that which reveals itself to our observation, as existent, but also to signify that which only seems to be, in contrast to that which truly is. There is thus not merely a certain vagueness in the word, but it even involves a kind of contradiction to the sense in which it is used when employed for *phænomenon.* In consequence of this, the term *phænomenon* has been naturalized in our language as a philosophical substitute for the term appearance.
Sir W. Hamilton, Metaph., viii.

A *phenomenon,* as commonly understood, is what is manifest, sensible, evident, the implication being that there are eyes to see, ears to hear, and so forth.

And do we need any more evidence to convince us that *phenomena*—by which I mean the effects produced upon our consciousness by unknown external agencies—are all that we can compare and classify, and are therefore all that we can know? *J. Fiske,* Cosmic Philos., I. 20.

In fiction, the principles are given, to find the facts; in history, the facts are given, to find the principles; and the writer who does not explain the *phenomena* as well as state them performs only one half of his office.
Macaulay, History.

We do not inquire respecting this human nature what are the laws under which its varied *phenomena* may be generalized, and accommodate our acts to them.

=Syn. *Philanthropy*, *Charity*. Originally these words were the same, meaning the love of fellow-man, a sense which *philanthropy* retains, but *charity* (except in Biblical language: see 1 Cor. xiii., authorized version) has lost. Each expresses both spirit and action; but *philanthropy* cannot be applied to a concrete act, while *charity* may; hence we speak of a *charity*, but not of a *philanthropy*; on the other hand, as a spirit, *philanthropy* looks upon human welfare as a thing to be promoted, especially by preventing or mitigating actual suffering, while *charity*, outside of Biblical usage, is simply disposed to take as favorable a view as possible of the character, conduct, motives, or the like, of a fellow-man. As activity, *charity* helps men individually; *philanthropy* helps the individual as a member of the race, or provides for large numbers. *Philanthropy* agitates for prison-reform and the provision of occupation for released convicts; *charity* gives a released convict such personal help as he needs.

Philology . . . deals with human speech, and with all that speech discloses as to the nature and history of man.
Whitney, Encyc. Brit., XVIII. 765.

Comparative philology, the study of languages as carried on by the comparative method; investigation, by means of a comparison of languages, of their history, relationships, and characteristics, within narrower or wider limits; linguistic science; linguistics; glossology.

Philology, whether classical or oriental, whether treating of ancient or modern, of cultivated or barbarous languages, is an historical science. Language is here treated simply as a means. The classical scholar uses Greek or Latin, the oriental scholar Hebrew or Sanskrit, or any other language, as a key to an understanding of the literary monuments which bygone ages have bequeathed to us, as a spell to raise from the tomb of time the thoughts of great men in different ages and different countries, and as a means ultimately to trace the social, moral, intellectual, and religious progress of the human race. . . . In *comparative philology* the case is totally different. In the science of language, languages are not treated as a means; language itself becomes the sole object of scientific inquiry. Dialects which have never produced any literature at all, the jargons of savage tribes, the clicks of the Hottentots, and the vocal modulations of the Indo-Chinese, are as important, nay, for the solution of some of our problems, more important, than the poetry of Homer or the prose of Cicero. We do not want to know languages, we want to know language; what language is, how it can form a vehicle or an organ of thought; we want to know its origin, its nature, its laws, and it is only in order to arrive at that knowledge that we collect, arrange, and classify all the facts of language that are within our reach.
Max Müller, Science of Language, 1st ser., Lect. 1.

'one who loves wisdom' (a term first used, according to the tradition, by Pythagoras, who preferred to call himself *φιλόσοφος*, one who loves wisdom, instead of *σοφός*, a sage); in later use (Hesychius) in the sense 'loving a handicraft or art'; < *φιλεῖν*, love, + *σοφία*, wisdom, skill, art, < *σοφός*, wise, skilful: see *sophist.*] 1. The body of highest truth; the organized sum of science; the science of which all others are branches; the science of the most fundamental matters. This is identified by different schools—(*a*) with the account of the elementary factors operative in the universe; the science of principles, or the matter, form, causes, and ends of things in general; (*b*) with the science of the absolute; metaphysics; (*c*) with the science of science; the theory of cognition; logic. In Greek, *philosophy* originally signified culture; but from Aristotle down it had two meanings—(*a*) speculative knowledge, and (*b*) the study of the highest things, metaphysics. Chrysippus defined it as the science of things divine and human. In the middle ages philosophy was understood to embrace all the speculative sciences: hence the faculty and degree of arts in German universities are called the faculty and degree in philosophy.

In *philosophy*, the contemplations of man do either penetrate unto God or are circumferred to nature, or are reflected or reverted upon himself. Out of which several inquiries there do arise three knowledges, divine *philosophy*, natural *philosophy*, and human *philosophy*, or humanity. *Bacon*, Advancement of Learning, ii.

Philosophy has been defined:—The science of things divine and human, and the causes in which they are contained;—The science of effects by their causes;—The science of sufficient reasons;—The science of things possible, inasmuch as they are possible;—The science of things, evidently deduced from first principles;—The science of truths, sensible and abstract;—The application of reason to its legitimate objects;—The science of the relations of all knowledge to the necessary ends of human reason;—The science of the original form of the ego or mental self;—The science of science;—The science of the absolute;—The science of the absolute indifference of the ideal and real. *Sir W. Hamilton*, Metaphysics, iii.

All knowledge of reason is . . . either based on concepts or on the construction of concepts; the former being called philosophical, the later mathematical. . . . The system of all philosophical knowledge is called *philosophy*. It must be taken objectively, if we understand by it the type of criticising all philosophical attempts, which is to serve for the criticism of every subjective *philosophy*, however various and changeable the systems may be. In this manner *philosophy* is a mere idea of a possible science which exists nowhere in the concrete, but which we may try to approach on different paths. . . . So far the concept of *philosophy* is only scholastic. . . . But there is also a universal, or, if we may say so, a cosmical concept (conceptus cosmicus) of *philosophy*, which always formed the real foundation of that name. . . . In this sense *philosophy* is the science of the relations of all knowledge to the essential aims of human reason.
Kant, Critique of Pure Reason (tr. by Müller), II. 719.

Philosophy is an all-comprehensive Synthesis of the doctrines and methods of science; a coherent body of theorems concerning the Cosmos, and concerning Man in his relations to the Cosmos of which he is a part.
J. Fiske, Cosmic Philos., I. 9.

It is only after Stahl's [1660–1734] labors that a scientific chemistry becomes for the first time possible; the essential difference between the teaching of the science then and now being that the phenomena of combustion were then believed to be due to a chemical decomposition, *phlogiston* being supposed to escape, whilst we account for the same phenomena now by a chemical combination, oxygen or some element being taken up.

Cf. *Deimos.*] The inner of the two satellites of the planet Mars, discovered by Asaph Hall at Washington, in August, 1877. This extraordinary body revolves in the plane of the equator of Mars, at a distance of only about 3,700 miles from the surface of the planet, but as it is probably only about five and a half miles in diameter, it would appear only one sixth of the apparent diameter of our moon at the zenith, and on the horizon, owing to the enormous parallax, only about one fourteenth of the same. At the equinoxes it is in eclipse about one fifth of the time, or double that proportion of the time between sunset and sunrise. At the solstices it does not suffer eclipse. It revolves about its primary in 7 hours, 39 minutes, and 14 seconds, and as Mars revolves on its axis in 24 hours, 37 minutes, and 22.7 seconds, it follows that the satellite appears to an observer on Mars to rise in the west and set in the east, its return to his meridian occurring in 11 hours, 6 minutes, and 23 seconds, but, owing to its close proximity, its velocity will appear to be much greater. At a station on the equator of Mars (where the satellite always passes through the zenith), it will, out of its 11 hours and 6 minutes of period, pass only 3 hours and 20 minutes above the horizon against 7 hours and 46 minutes below.

The 12 species are the cultivated and the wild date-palms, all natives of the Old World, within or near the tropics of Asia and Africa. The habit of different species varies greatly, the trunks being either short or tall, robust or slender, erect or declined. The trunk is destitute of spines, but is commonly covered with the persistent leaf-bases. The palms grow in close clusters, forming groves. The pinnate leaves are large and terminal, forming a spreading canopy, each consisting of very numerous narrow, rigid, and compressed leaflets, the lower ones shorter and transformed into spines. The abundant yellow and rather small flowers have three sepals and three petals. The staminate trees bear oblong or ovoid flowers on numerous erect and much-branched spadices between the upper leaves. The pistillate trees bear spherical flowers on similar but often nodding spadices, followed by numerous cylindrical orange, brown, or black berries, those of *P. dactylifera* being the dates of commerce. (For this fruit, see *date-palm* and *date*³; and for the sugar made from it, see *jaggery* and *goor*.) This species is the chief palm of history and of ceremony, having been used as the emblem of triumph from the Egyptian worship of Isis onward. It is the palm of ancient Palestine, and has been for centuries cultivated for miles along the Italian and French Riviera, to supply palm-branches for festivals. White palm-branches are procured by binding the top of the unfolding leaf-bud, thereby blanching the inner leaves. It does not fruit in Italy nor under glass, and requires for successful growth an average annual temperature of 80° F. In Africa native huts are made from its leaves, its wood is used for building, its fiber for cloth and ropes, its leaf-stalks for brooms, crates, etc., its young leaves are eaten, and an intoxicating drink is made from its sap. It reaches a height of 80 and rarely 120 feet, and bears fruit, though in diminishing abundance, for as long as 200 years. The necessity of artificially fertilizing it first drew attention to the existence of sex in plants. *P. sylvestris*, the wild date-palm of India and Africa, is smaller, reaches a height of 40 feet, bears yellow or reddish berries, and is an important source of sugar and toddy, both prepared from its sap, which it is said can be made to flow from the upper part of its trunk for twenty years. *P. humilis*, a dwarf from southern China, and *P. reclinata*, a decumbent palm from the Cape of Good Hope, also bear sweet edible berries, and are valued, as is *P. paludosa*, a stout Indian tree, for decorative uses. See *Palmæ*2.

They are related to the *Anatinidæ*. The mantle-margins are mostly united, and the siphons long and united; the foot is small, with a small process bifurcated behind, and the branchiæ are thick and appendiculate. The shell is equivalve, very thin, nacreous internally and with radiating ribs, without hinge-teeth, and with an external ligament. The living species are few, and are found only in very deep water, but in former ages they were very numerous.

phonogram (fō'nō-gram), *n.* [< Gr. *φωνή*, sound, voice, + *γράμμα*, a writing, letter: see *gram*[2].] 1. A graphic character representing a sound of the human voice.

An instrument invented by Thomas A. Edison in 1877 for recording and reproducing speech, music, and other sounds. By means of a suitable mechanism the sound vibrations

are recorded by being made to produce permanent and characteristic indentations or incisions in an impressible registering material. Through a somewhat similar mechanism, made to engage with these indentations or incisions, the original vibrations are reproduced, thus reproducing the original sounds. Edison's first working model of the phonograph is shown at A. It comprised a metallic cylinder having a helical indenting groove cut upon it from end to end. This cylinder was mounted on a threaded shaft supported on two standards. The shaft at one end was fitted with a handle by means of which the

cylinder was rotated. There were two diaphragms, one on each side of the cylinder; one being for recording and the other for reproducing speech or other sounds. Each diaphragm had attached to it a needle. By means of the needle attached to the recording diaphragm, indentations were made in a sheet of tin-foil stretched over the peripheral surface of the cylinder when the diaphragm was vibrated by reason of speech or other sounds. The needle on the other diaphragm was made subsequently to follow these indentations, thus causing this diaphragm to repeat the original vibrations and by that means to reproduce the original sounds. The modern phonograph operates under precisely similar principles, the only difference being in details of arrangement and in refinement. As an impressible material, a wax cylinder is employed, instead of tin-foil, and the sound record is cut thereon with a tiny sapphire cutting-tool attached to a diaphragm. The reproduction is effected by means of a minute blunt stylus, also made of sapphire, and similarly attached to a reproducing diaphragm, through which the original sounds are reproduced in the manner above mentioned. The modern phonograph is illustrated at B.

The representation of words as they are pronounced; specifically, a system of phonetic writing in shorthand introduced by Sir Isaac Pitman of Bath, England, in the year 1837. The consonants are represented by simple lines (called stems), curved or straight, light or heavy, vertical, horizontal, or slanting, with initial and terminal hooks, circles, loops, etc.; the vowels are represented by dots and dashes, light or heavy, by combinations of them, and by small angles and semicircles. In actual use most of the vowel-signs are omitted (though they may in many cases be approximately indicated by the position—above, on, or below the line—of the consonant-stem), and the consonant-stems, by halving, doubling, etc., are made to perform extra duty. For further brevity, various devices are employed. See *short-hand*.

3. The recording of sound by mechanical means, with a view to its reproduction.

phonolite (fō'nō-līt), *n.* [= F. *phonolithe* = Pg. *phonolite*; equiv. to *clinkstone*; < Gr. *φωνή*, sound, + *λίθος*, stone.] In *petrog.*, the name applied to volcanic rocks of porphyritic or felsitic habit, consisting essentially of alkali feldspar (orthoclase or anorthoclase), nephelin, and a pyroxene or amphibole. Closely related to trachyte both in texture and composition, but with less silica, hence the formation of nephelin. The name was proposed by Klaproth (1801) to replace the common term *clinkstone*. The texture of phonolite is commonly very compact, but it generally splits easily into shard-like pieces which ring on being struck. The dull greenish rock weathers easily to a light gray color. Associated with nephelin are often one or more of the allied soda minerals, nosean, haüyne or sodalite, and the potash mineral leucite, leading to the names *nosean-phonolite*, etc. Phonolite is a rock unusually rich in soda, and its characteristic pyroxene, ægirite, contains a considerable amount of this alkali, as do the amphiboles riebeckite and arfvedsonite, which are sometimes found in the rock. It is characteristic of phonolite, as a nephelin-bearing rock, that on treating its powder with hydrochloric acid there is a very distinct formation of gelatinous silica. Phonolite is equivalent in chemical composition to elæolite-syenite. It is abundant in Bohemia, the Eifel district in Germany, and in many other localities. In the United States it occurs in the Cripple Creek district, Colorado.

The simplest form comprises apparatus for uniformly moving a paper tape coated with lampblack, in contact with a delicate tracing-point fixed to the vibrating body. By this means an undulating curve is traced having a length corresponding to the time of its motion. The number of undulations in the curve is also the number of vibrations made by the sounding string or fork. Phosphorescence is sometimes a chemical, sometimes a physical action. When chemical, it consists essentially in slow oxidation attended with evolution of light, as in the case of phosphorus. When physical, it consists in the continuation of the molecular vibrations causing the emission of light after the body has ceased to be exposed to the radiation to which this motion is due; this is seen in the case of the diamond, chlorophane, sugar, barium and calcium sulphids, and many other substances. Phosphorescence is produced in many substances by exposure to the electrical discharge in a vacuum-tube, to X-rays, cathode rays, or the rays from radium salts. The phosphorescence of the sea is produced by the scintillating or phosphorescent light emitted from the bodies of certain marine animals. The luminosity of plants is a condition under which certain plants (always, so far as now known, *Thallophytes*) evolve light. The so-called luminosity or phosphorescence of decaying wood is due to the presence of the mycelium of *Agaricus melleus.* Other luminous fungi are *Agaricus olearius*, *A. igneus*, *A. noctilus*, and *A. Gardneri.* Various algæ and diatoms also exhibit this phenomenon. See cut under *Noctiluca.*

> What is correctly termed *phosphorescence* has nothing to do with phosphorus, but it is merely a species of fluorescence. *Tait*, Light, § 204.

Various animals are phosphorescent; as, among infusorians, the noctilucas (*see* cut under *Noctiluca*); among polyps, certain sea-pens (*Pennatula phosphorea*, for example); among insects, the glow-worm and other beetles of the family *Lampyridæ* (see cuts under *firefly*, *Lampyris*, and *lightning-bug*), and many bugs of the family *Fulgoridæ* (see cut under *lantern-fly*); among ascidians, the pyrosomes or firebodies; and some fishes. Many substances exhibit phosphorescence after exposure to light or to some one of the exciting agents mentioned above, as calcium chlorid, anhydrous calcium nitrate, the sulphids of barium, strontium, calcium (luminous paint), the diamond, some varieties of fluor-spar, apatite, borax, etc. Some mineral bodies become phosphorescent when strongly heated. See *phosphorescence.* — **Phosphorescent dial, paint, photograph**, etc. See the nouns.

Glacial phosphoric acid. See *glacial*.—**Phosphoric acid,** H_3PO_4 (properly called *orthophosphoric acid* in contradistinction to *metaphosphoric acid*), an acid usually obtained by decomposing bone-ash, which consists chiefly of calcium phosphate, with sulphuric acid, and separating from foreign matters the phosphoric acid thus liberated. It is also produced by the oxidation of phosphorous acid, by oxidizing red phosphorus with nitric acid, by the decomposition of apatite and other native phosphates, and in various other ways. It is a colorless odorless syrup, with an intensely sour taste. It is tribasic, forming three distinct classes of metallic salts. The three atoms of hydrogen may in like manner be replaced by alcohol radicals, forming acid and neutral ethers. Phosphoric acid is used in medicine as a tonic.

An instrument for measuring the duration of evanescent phosphorescence in different substances. It consists of a hollow black metal box within which is placed the object to be tested. The ends of the box have each an aperture, the two being opposite each other and of the form of a circular sector. The box is traversed by a movable axis carrying two circular screens each of which has four perforations of the shape of the apertures in the box; but while those of the box correspond with each other, the latter alternate. The object to be tested is supported in front of the apertures of the box and between the screens which are rotated by guard wheels at any desired speed. The substance can thus be exposed alternately to a light behind the box and to the eye.

2. Chemical symbol, P; atomic weight, 31; specific gravity, 1.826. A solid non-metallic combustible substance, hitherto undecomposed, not found by itself in nature, but occurring chiefly in combination with oxygen, calcium, and magnesium. It is widely distributed, being an essential constituent of all plants and of the bony tissue of animals. It was originally obtained from urine; but it is now manufactured from bones, which consist in large part of calcium phosphate. Common phosphorus, when pure, is semi-transparent and colorless. At common temperatures it is a soft solid, easily cut with a knife, the cut surface having a waxy luster; at 112° F. it fuses, and at 550° is converted into vapor. It is soluble, by the aid of heat, in naphtha, in fixed and volatile oils, and in sulphur chlorid, carbon disulphid, and phosphorus sulphid. It is exceedingly inflammable. Exposed to the air at common temperatures, it undergoes slow combustion, emits a white fume of a peculiar garlic odor, and appears luminous in the dark. A very slight degree of heat is sufficient to inflame it in the open air. Gentle pressure between the fingers, friction, or a temperature not much above its point of fusion kindles it readily. It burns rapidly even in the air, emitting a splendid white light, and causing intense heat. Its combustion is far more rapid in oxygen gas, and the light far more vivid. The product of the perfect combustion of phosphorus is phosphorus pentoxid (P_2O_5), a white solid which readily takes up water, passing into phosphoric acid (which see, under *phosphoric*). Phosphorus may be made to combine with most of the metals, forming compounds called *phosphides;* when dissolved in fat oils it forms a solution which is luminous in the dark. It is chiefly used in the preparation of lucifer matches, and in the preparation of phosphoric acid. It is used to some extent in medicine in nervous affections, but is virulently poisonous except in very minute doses. Phosphorus presents a good example of allotropy, in that it can be exhibited in at least one other form, known as *red* or *amorphous phosphorus*, presenting completely different properties from common phosphorus. This variety is produced by keeping common phosphorus for a long time slightly below the boiling-point. It is a red, hard, brittle substance, not fusible, not poisonous, and not readily inflammable, so that it may be handled with impunity. When heated to the boiling-point it changes back to common phosphorus.—**Bologna, Bolognian,** or **Bononian phosphorus,** one of the most powerful of the solar phosphoric substances. It is prepared by heating barium sulphate intensely with powdered charcoal, and filling with it while hot glass tubes, which are at once sealed. After exposure to sunlight, the mass phosphoresces in the dark with a bright orange-colored light.—**Phosphorus bottle.** (*a*) A contrivance for obtaining instantaneous light. The light is produced by stirring a piece of phosphorus about in a dry bottle with a hot wire, and introducing a sulphur match. It is now superseded by lucifer matches and similar contrivances. (*b*) A small bottle containing 12 grains of phosphorus melted in half an ounce of olive-oil. On being uncorked in the dark this solution emits light enough to illuminate the dial of a watch, and it will retain this property for several years if not too frequently used.—**Phosphorus paste,** a poisonous compound containing phosphorus, for the destruction of vermin, as rats, mice, cockroaches, etc.

The gas so prepared is spontaneously inflammable, owing to the presence of traces of vapor of a liquid hydrid of phosphorus, and during its combustion there are formed water and phosphoric acid. The pure gas, while very combustible, does not inflame spontaneously; it is colorless, is very poisonous, and has a disgusting smell, resembling that of decaying fish. When mixed with oxygen gas it explodes by reduction of pressure. It is produced by the decomposition of animal substances. When this gas is cooled below zero (C.) it deposits a liquid, hydrogen phosphide; the gaseous phosphide remaining is no longer spontaneously inflammable. Also called *phosphine*.

photo-engraving (fō″tō-en-grā'ving), *n.* [< Gr. φῶς (φωτ-), light, + E. *engraving.*] A common name for many processes by which plates for use in a printing-press can be produced through the medium of photography. These processes depend upon the property, possessed by potassium bichromate and analogous chemicals, of rendering insoluble, under the action of light, gelatin or some similar body with which they are compounded. By applications of this property, varying according to the process, a picture or design can be produced on a metal surface, and the blank places etched out with acid; from this a matrix can be formed, from which an electrotype plate can be made in the ordinary ways. In general, the term *photo-engraving* is limited to a relief-block or -plate produced by photographic means for printing in an ordinary printing-press, to the art of making such blocks, and to prints from them; while the term *photogravure* is commonly applied to a photographically engraved plate in intaglio from which prints may be taken in a copperplate-press, to the art of making such an incised plate, and to a print from it. In the Gillet process a zinc plate coated with asphaltum is exposed beneath a negative, and the portions unchanged by light are dissolved. The zinc is then etched. Photographs are reproduced in the form of half-tone plates for use in the printing-press by several methods, all of which depend upon breaking up the surface of the picture by dark lines in regular series. A gelatin film on which such a series of lines has been photographed is placed between the sensitized surface which is to receive the impression and a positive picture. The resulting print will consist of the subject appearing in half-tone on a ground of lines, and from it a typographical matrix can be prepared for electrotyping in the usual ways. (For an example of a half-tone plate, see cut under *dekadrachm.*) Also called *photographic engraving, photographic-process printing, photographic process.* See *photo-etching* (Gillet process), and compare *heliotypy* and *photogravure.*

photography (fō-tog'rȧ-fi), *n.* [= F. *photographie* = Sp. *fotografía* = Pg. *photographia* = It. *fotografia* = D. *photografie* = G. *photographie* = Sw. Dan. *fotografi*, photography (in Sp. Pg. It. also a photograph), = NGr. φωτογραφία, photography, < Gr. φῶς (φωτ-), light, + *-γραφία*, < γράφειν, write. Cf. *photograph.*] The art of producing images of objects by an application of the chemical change produced in certain substances, as silver chlorid, bromide, or iodide, by the action of light, or more generally of radiant energy. The rays which are in general most active in this way are those of the upper part of the spectrum, as the blue, violet, and ultra-violet rays. The red and yellow rays produce a much less marked effect on an ordinary sensitive plate; but it has been found possible to prepare a special gelatinobromide plate which is highly sensitive even to the less refrangible rays, as those in the infra-red region of the spectrum. (See *spectrum.*) Photography rests on the fact that silver nitrate and various other chemicals are decomposed by certain solar rays and reduced, becoming dark or black, or in other ways affected, according to the intensity and amount of actinic rays received on them. The process consists (1) in properly exposing a surface made sensitive to actinic rays to a projected image of the object to be reproduced; (2) in rendering visible if merely latent, or in coloring or toning, the reproduction of this image; (3) in removing the sensibility of those parts of the surface which have not been acted on, and in fixing permanently the image produced; and (4), if the image obtained is a negative, as in the majority of processes, in the mechanical production of positive copies from it. The knowledge of the principle on which photography depends reaches back to the time of the alchemists, who discovered that silver chlorid exposed to the sun's rays became black. Wedgwood and Davy in 1802 attempted to apply this fact to artistic purposes by throwing the shadow of an object on a sheet of white paper, or, preferably, of leather, covered with a solution of silver nitrate and exposed to the sun's rays, but they were unable to fix the pictures. About 1814 Niepce, a Frenchman, discovered a method of producing pictures on plates of copper or pewter covered with a sensitive resinous substance called bitumen of Judea, and also of rendering them permanent. This process he called *heliography.* Niepce associated himself with Daguerre, who elaborated, about 1838, from the former process the one which bears his name. (See *daguerreotype.*) This was soon superseded by various processes, especially the *calotype process* (see *calotype*) of Fox-Talbot, first patented in 1841, who revived Wedgwood's process of obtaining pictures on sensitized paper, and the *collodion process* (see *collodion*), first suggested by M. Le Grey, of Paris, and brought into practice by Archer in 1850; and all these later processes have been practically abandoned for the *gelatinobromide dry-plate process,* which is now in almost universal use. Photographs produced by any of these processes may be either *negative* or *positive.* Negative photographs exhibit the lights and shades as opposite to those in nature—that is, the lights appear dark and the shades transparent; positive photographs exhibit the lights and shades in accordance with nature. To produce a positive from a negative, the latter is placed in contact with a surface which has been rendered sensitive to light, and is exposed to the influence of light, which penetrates the negative and affects the parts of the underlying surface opposite the lights of the picture, while the parts opposite the opaque parts of the picture are protected. The operation for obtaining a positive from a negative is called *printing.* Modifications are constantly being introduced in photography. One of the most important has been the *carbon process,* popularized by Swan of Newcastle, according to which a solution of gelatin and potassium bichromate (the latter being the sensitizing agent) is mixed with a pigment, and applied as a coating to a sheet of paper. The positives are printed in the ordinary way on the black cake, or *tissue* as it is called, thus produced, and become visible and permanent by washing, as the pigment-coating is rendered more or less insoluble by the effect of the light passing through the negative. The *autotype process,* invented by Johnson, is a simpler method of carbon-printing than the carbon process proper, but the principles involved are the same. One of the most important developments of the art is the so-called *instantaneous photography,* by means of which, through the use of very sensitive plates and the shortness of the duration of exposure,

scenes, motions, etc., are reproduced and registered which are too rapid or evanescent to be distinguishable by the eye. For various mechanical methods of multiplying photographic pictures, see *photo-electrotype*, *photo-engraving*, *photogalvanography*, *photoglyphy*, *photogravure*, *photolithography*, and *heliotypy*.

★**photogravure** (fō″tō-grā-vūr′), *n.* [< F. *photogravure*, < Gr. φῶς (φωτ-), light, + F. *gravure*, engraving.] The art of producing on metal, by an application of the action of light on a sensitized surface, often supplemented by etching, an incised engraved plate for printing. There are several processes by which this may be accomplished. According to the Niepce process, which is suitable for the reproduction of line-engravings, a copperplate is coated with a mixture of fish-glue and bichromate of ammonia, and is then exposed to light beneath a positive. The resulting print is brought out with water, which dissolves the parts not acted on by light, and the lines remain as bare copper exposed for action of the etching acid. In the Fox-Talbot process the gelatin print is transferred to copper which has had a grain given to it by sprinkling the surface with powdered resin and then warming it. (See *aquatint*.) The plate is then etched with ferric acid, which renders the opaque portions of the gelatin film insoluble and impermeable. The acid should be weak and kept in motion during the biting, until the uncovered parts have been sufficiently attacked. To increase the regularity of the erosion, the plate should first be immersed in a weak solution of copper sulphate. In the Woodbury process, which resembles the Goupil process, a gelatin picture in relief is applied under pressure upon a plate of soft metal, and is repeated on the metal in relief and depression. The mold thus formed is filled with pigmented gelatin, over which a sheet of paper which is to receive the picture is placed, and subjected to a level pressure in order to force out the superfluous gelatin. The depressed parts, which represent the dark parts of the picture, retain the most gelatin, and when the paper is lifted it raises the gelatin from the mold in such a manner that it forms a picture in low relief. In order to obtain a grained surface which will hold printing-ink, pounded glass may be mixed with the gelatin.

Many forms have been devised, most of which are based upon the determination of the relative distances

a, balance by which weight of candles burned in a given time is determined; *b*, candles; *g*, clock, and meter which measures the gas consumed in the test; *f*, gas-burner; *h*, flexible pipes for supplying gas to the burner; *d*, sight-box, supported on a carriage *s*; *e*, scale having a guide-way for the carriage of the sight-box, and graduated to show the relative candle-power of gas which gives an illumination having intensity equal to that of the candles. This graduation corresponds with the position of the sight-box when the latter is adjusted so that equal intensity is obtained on both sides of the disk; *c* is a curtain to exclude other light during the adjustment of the sight-box; *r*, cord running over pulleys under the bottom of the instrument, by which an operator can start or stop the clock at the beginning and end of the test; *k*, disk, with the translucent serrated spot *l*; *m*, sight-tube; *o o′*, mirrors. Light enters the sight-box from the candles through the opening *q* in the side of the sight-box, and from the gas-burner on the side of *n*. Images of both sides of the illuminated disk are simultaneously seen at *n n′* by reflection from the mirrors at *o* and *o′*.

at which the light from two sources produces equal intensities of illumination. One of the most common photometers is that of Bunsen, which consists of a screen of white paper with a grease-spot in its center. The lights to be compared are placed on opposite sides of this screen, and their distances are so adjusted that the grease-spot appears neither brighter nor darker than the rest of the paper, from whichever side it is viewed. When the distances have not been correctly adjusted, the grease-spot will appear darker than the rest of the paper when viewed from the side on which the illumination is most intense, and lighter than the rest of the paper when viewed from the other side. The intensities of the two lights are to one another as the squares of the distances from the screen at which they must be placed in order that the grease-spot may appear neither brighter nor darker than the rest of the paper. Another form is Rumford's photometer, which employs a screen in front of which is placed a vertical rod; the positions of the sources of light are so adjusted that the two shadows which they cast are sensibly equal.—**Dispersion photometer**, a form of photometer by means of which the intensity of a brilliant light, as that of an electric arc, may be determined. The dispersive effect of a thin concave lens acts like increase of distance in the common photometer to weaken the bright light to the required degree.—**Polarization photometer**, an instrument in which the measurement depends upon the properties of polarized light.—**Wedge photometer**, an astronomical photometer in which a wedge of neutral-tinted dark glass is used to cause the apparent extinction of a star viewed through it. The thickness of the wedge at the point where the star vanishes determines its brightness.—**Wheel photometer**, an instrument in which the light to be measured is weakened in any required degree by transmission through adjustable apertures in a rapidly ★revolving wheel.

photometric (fō-tō-met′rik), *a.* [= F. *photométrique* = Pg. *photometrico*; as *photometr-y* + *-ic*.] Pertaining to photometry, or the measurement of the intensity of light, or to the photometer, or instrument by which this is effected; employing or made by a photometer: as, *photometric* researches or observations.—**Lambert's photometric law** [named after Johann Heinrich *Lambert* (1728–77), an eminent mathematician], the law that the light which each element of a luminous surface, or of a diffusely reflecting surface, reflects is proportional to the cosine of the angle of emanation.—**Photometric standard**, a carcel lamp burning 42 grams of refined colza-oil per hour, with a flame 40 millimeters high. It is equal to 9.5 British or 7.6 German standard candles. The *unit of photometry* adopted by the Electrical Congress at Paris (1884) is the amount of light emitted from a surface of one square centimeter of melted platinum at its temperature of solidification; in 1889 one twentieth of this unit was adopted as the practical unit, and called a *candle*. photophone (fō′tō-fōn), *n.* [< Gr. φῶς (φωτ-), light, + *φωνή*, sound, voice: see *phone*[1].] An instrument by which a beam of light may be made to transmit spoken words to a distance.

One form consists of a thin mirror of silvered mica which receives the vibrations from the person speaking, and upon which a beam of light falls at the same time. This light is reflected to the receiving-point at a distance. There it falls upon a concave mirror, and is brought to a focus upon a selenium-cell. The variation in the light produces a corresponding variation in the electrical resistance of the selenium, and this reproduces the spoken words in a telephone connected with it.

In the earlier papers describing it [the radiophone] and the experiments which led to its invention it is called *photophone*, because at that time the effects were supposed to be wholly due to light. Afterwards, in order to avoid ambiguity, Bell changed the name to radiophone, and suggested that, to distinguish between instruments depending on the different kinds of radiation, the names *photophone*, thermophone, &c., should be employed.

It has a doubly refracting prism mounted at one end of a tube, which at the other has a diaphragm of such size that the borders of the two images, polarized at right angles, just coincide with each other. A nicol prism suitably mounted is made to revolve until these images have the same intensity, when the angular position of its plane of vibration gives a ready means of determining the degree of polarization in the light under examination.

photo-process (fō'tō-pros″es), *n.* [< Gr. *φῶς* (*φωτ-*), light, + E. *process.*] Any process or method by which is produced, by the agency of photography, a matrix in relief or in intaglio from which prints can be made in ink; especially, the photographic production of relief-plates from which impressions are struck off in an ordinary printing-press. It thus includes photogravure, but is especially applicable to such processes of photo-engraving as photolithography and photozincography. The chief kinds of photo-process are differentiated as follows. Heliotype is the production of a matrix in gelatin, from which printing is done directly in a lithographic press. Photogravure is the production of incised or intaglio plates in metal. Photo-engraving is (properly) the production of relief-plates of any kind suited for printing, together with type, in an ordinary printing-press; though the term is often used to include photogravure also. Photo-engraving is particularly applicable to the reproduction of pen-drawings; when used for pictures, such as ordinary photographs, it is necessary, in order to admit of printing, to employ some such device as the formation over the whole surface of the plate of an even series of fine lines, or a finely dotted or stippled ground. Such plates are called *half-tone plates.* (See *half-tone process*, under *photo-engraving.*) Also used attributively to note a relief-plate, or an impression from such a plate, made by photo-process.

The person whose likeness is to be taken is placed in the focus of a number of photographic cameras, placed at equal distances from one another, and is thus photographed all round. The resulting pictures are projected in succession by means of a magic lantern on a transparent screen. The operator works behind this screen on a piece of modeling-clay, turning it round as he proceeds, and copying the images on the screen by means of a pantograph which has its reducing-point armed with a molding- or cutting-tool, so that, as the longer arm traces every figure on the screen, the shorter one reproduces it in the clay.

According to Kirchhoff, the sun's photosphere is either solid or liquid, and is surrounded by an extensive atmosphere, composed of gases and vapors of the substances incandescent in the photosphere. According to the view now more generally accepted, the photosphere is a shell of luminous cloud — that is, the solid or liquid particles which produce the light are minute, and disseminated through the lower strata of the solar atmosphere.

In Australia the *phratries* are still more important than in America. Messrs. Howitt and Fison, who have done so much to advance our knowledge of the social system of the Australian aborigines, have given to these exogamous divisions the name of classes; but the term is objectionable, because it fails to convey (1) that these divisions are kinship divisions, and (2) that they are intermediate divisions; whereas the Greek term *phratry* conveys both these meanings, and is therefore appropriate.

The theory that the mental powers of the individual consist of independent faculties, each of which has its seat in a definite brain-region, whose size is commensurate with the power of manifesting this particular faculty. This theory, which originated at the close of the eighteenth century, assumes, moreover, as an essential part, the plasticity of the cranial envelop, by which the skull conforms externally, in the normal subject, to the shape and configuration of the brain within, so that its form and faculties may be determined, with sufficient exactness, from the skull itself, whether in the skeleton or in the living person. The different powers of the mind or faculties are divided into two classes, the feelings and the intellect, or the affective and intellectual faculties, the former of which is again divided into the propensities and sentiments, the latter into the perceptive and reflective faculties. Each of these groups, as well as each of the individual faculties composing them, is located upon the exterior of the skull with more or less exactness, and it is by the prominence or depression of the different regions that the mental powers and faculties are ascertained. The system was founded by Dr. Franz Joseph Gall (1758–1828), a Viennese physician, and was extended and promulgated by his pupil and associate, Dr. Spurzheim, and by George and Andrew Combe and others. The term is sometimes applied, in the phrase *new phrenology*, to the localization of cerebral functions which has been established by experimental and pathological investigations, almost exclusively of the last twenty years, and which has reached such a degree of certainty and definiteness as to furnish a basis for surgical operations on the brain. But there is nothing in common between modern cerebral localization and the views of Gall and Spurzheim. See cut in next column.

It is an erect herb, with a few stiff straggling branches, opposite toothed leaves, and a long slender spike of small scattered purplish flowers, at first erect, then spreading, and in fruit reflexed, whence its popular name, *lopseed.* The fruit is a small, dry, short-stalked utricle, hooked at the apex, and adapted to distribution by catching in the hair of animals.

is usual in related lizards. The head is surmounted with several pairs of stout spines, largest in some of the southerly and Mexican forms, and the whole upper surface of the body is roughly granular or tuberculous; the under side is smooth. The coloration of the upper parts is variegated with black, brown, gray, and reddish, in a blotched pattern, and varies greatly, not only with the different species, but in different individuals of the same kind. The creatures have nothing of the agility of most lizards; they are clumsy in their motions, rather sluggish, and cannot jump. They are perfectly harmless, become tame as soon as handled, and are often kept as pets for their oddity. They feed on flies and other insects, but can fast long, and may be safely sent by mail alive to any part of the United States. [NL., < Gr. *φυλή*, a body of men joined by ties of birth, a tribe, clan, class, phyle (cf. *φῦλον*, a tribe: see *phylum*), < *φύειν*, produce, *φύεσθαι*, grow: see *be*¹.] In ancient Greece, a tribe or clan; one of the subdivisions normally based on ties of blood, of which the aggregate constituted a community. In Athens the tribes did not rest on family relationship, but were at first geographical divisions, then classes formed according to occupation or wealth. Clisthenes abolished the old tribes, and distributed his fellow-citizens among ten new ones, named after ancient Attic heroes, and arranged upon geographical lines and democratic ideas; and this arrangement persisted through the glorious time of Attic history. Every full citizen of Athens was registered in a phyle, in a deme, and in a phratry. Every phyle was a political unit, to which were allotted the choice of 50 of the 500 senators and that of its due proportion of dicasts and of the higher civil and military officers of the state; and every phyle was required to contribute in a fixed proportion to the military service, to the various liturgies, etc.

★**phyletic** (fī-let′ik), *a.* [< Gr. *φυλετικός*, < *φυλέτης*, a tribesman, < *φυλή*, a tribe: see *phyle*.] 1. Pertaining to a race or tribe. Hence—2. In *biol.*, pertaining to a phylum of the animal kingdom, or to the construction of phyla; phylogenetic.

Each perithecium contains several 2- or rarely 3-spored asci, and the appendages are needle-shaped and abruptly swollen at the base. The only well-known species is *P. corylea*, which grows upon the leaves of a great variety of plants, especially woody plants.

phyllade (fil′ād), *n.* [< Gr. *φυλλάς* (*φυλλαδ-*), a bunch of leaves, < *φύλλον* = L. *folium*, leaf.] In *bot.*, one of the small imperfect leaves in *Isoëtes*, alternating with the fertile leaves. In the submerged species these consist of a small lamina with no sheath, and in the terrestrial species they are reduced to mere scales.

Phyllantheæ (fi-lan′thē-ē), *n. pl.* [NL. (Bartling, 1830), < *Phyllanthus* + *-eæ*.] A tribe of plants of the family *Euphorbiaceæ*, distinguished by carpels with two contiguous ovules in the central angle, and the seed-leaves much broader than the radicle. It includes 55 genera, mainly tropical, of which *Phyllanthus* is the type. For other principal genera, see *Putranjiva* and *Toxicodendron*.

Phyllanthus (fi-lan′thus), *n.* [NL. (Linnæus, 1737), so called from species with flowers seated on leaf-like flattened branches; < Gr. *φύλλον*, a leaf, + *ἄνθος*, flower (cf. L. *phyllanthes*, < Gr. *φυλλανθές*, a plant with prickly leaves, prob. scabious).] A large genus of plants, of the family *Euphorbiaceæ*, type of the tribe *Phyllantheæ*, characterized by the entire alternate leaves and apetalous monœcious flowers, the male in glomerate clusters and with from two to six stamens, and by the pistil consisting of from three to many carpels, their two-cleft styles not dilated below the apex. There are about 500 species, very widely dispersed throughout the warmer parts of the world, rarer in temperate climates. They are either herbs, shrubs, or trees, of great variety in appearance. The leaves are generally two-ranked, and so arranged as to make the branches resemble pinnate leaves. The small greenish flowers are axillary or at the nodes of leafless and often flattened branches, and are often tinged with yellow or purple. Several species are in medicinal repute as diuretics in India, as *P. Niruri* and *P. Urinaria*. The bruised leaves of *P. Conami* are there used to stupefy fish. Many species are cultivated under the name *leaf-flower*, from the blooming leaf-like branches, or cladodia. (See cut under *cladode*.) The snow-bush, cultivated for its white flowers, is *P. nivosus*, native of the New Hebrides. Many others are cultivated as ornamental evergreen shrubs under the names of *Emblica* and *Xylophylla*, the latter a numerous group of woody-branched shrubs with orange-red flowers, chiefly from the West Indies. For other species, see *Otaheite gooseberry* (under *gooseberry*), *laurel*, 3, and *myrobalan*. The last produces an edible fruit, used for preserves and in dyeing and tanning, and long famed as an astringent medicine (but not now so used), and a durable wood, used for implements, building, and furniture in India and Burma. The so-called Otaheite gooseberry is also known as star-gooseberry.

The males have long antennæ and wings, and can fly; the females have short antennæ, and are incapable of flight.

It has usually been further distinguished from a true blade by the statement that it normally presents the edges instead of the faces to the earth and sky; but recent investigation proves that this does not always hold good, since some undoubted phyllodia are not vertical, but are dorsiventrally placed, like true leaves. The South American *Oxalis bupleurifolia* is an example. Also *phyllode*. See also cut under *petiole*.

II. *n.* A crustacean of the order *Phyllopoda*.

Phyllopoda (fi-lop'ō-dä), *n. pl.* [NL.: see *phyllopod*.] 1. An order of entomostracous crustaceans, the leaf-footed crustaceans, sometimes forming (with *Ostracopoda* and *Cladocera*) a suborder of *Branchiopoda*. In Latreille's classification the phyllopods were a section of his branchiopods, corresponding to the modern order of *Phyllopoda*, and divided into (*a*) *Ceratophthalma*, with the genera *Limnadia* and *Estheria* (composing the modern family *Estheriidæ*) and *Artemia* and *Branchipus* (the modern family *Branchipodidæ*), and (*b*) *Aspidophora*, with the genera *Apus* and *Lepidurus* (the modern family *Apodidæ* or *Apusidæ*). The feet in phyllopods are very variable in number, and those of the locomotory series are membranous or foliaceous, as implied in the name. Excepting in *Branchipodidæ*, the body bears a very large carapace, which in the *Limnadiidæ* takes the form of a bivalve shell with a hinge, closed by adductor muscles, into which the legs can be withdrawn. But this carapace is not a cephalothorax as is usual in crustaceans. Two pairs of antennæ are usually present. The mouth-parts are a pair of mandibles, two pairs of maxillæ, and in some forms a pair of maxillipeds. Phyllopods hatch from the egg in the nauplius stage; in some of them parthenogenesis occurs, and the eggs are notable for their ability to withstand desiccation without losing their vitality. Phyllopods inhabit chiefly fresh-water ponds, sometimes swarming in vast numbers. The species of *Artemia*, as *A. salina*, are known as *brine-shrimps*. The phyllopods are an old type, going back to the Devonian, and have some resemblance to trilobites. See cuts under *Apus*, *Estheriidæ*, and *Limnetis*.

(Siebold and Zuccarini, 1843), so called with ref. to the leaf-bearing lower branches of the inflorescence; < Gr. *φύλλον*, leaf, + *στάχυς*, spike.] A genus of arborescent grasses, of the tribe *Bambuseæ* and subtribe *Arundinarieæ*, characterized by the one- to four-flowered spikelets, in spikes partly included within imbricated spathaceous bracts. They are tall grasses with cylindrical culms and prominent nodes, producing numerous dense or loose panicled spikes, and short-petioled leaves, jointed with the sheath and tessellated with little transverse veinlets. The 4 or 5 species are natives of China, Japan, and the Himalayas, resemble the bamboo, and furnish material for walking-sticks and bamboo chairs. *P. nigra* is the wanghee-cane of China, with black, nearly solid stems reaching 25 feet. *P. bambusoides* is a dwarf species from which yellowish canes are made.

Phyllosticta (fil-ō-stik′tą), *n.* [NL. The perithecia, which occupy discolored spots on the leaves, are minute, opening with a terminal pore. About 800 species have been described, which cause the well-known leaf-spot disease in many plants—*P. Catalpæ* on the catalpa, *P. pirina* on the apple, *P. Rosæ* on roses, *P. Ribis* on cultivated species of *Ribes*, *P. Labruscæ* on the grape (thought to be one form of the black rot), *P. minima* on the maple, etc.

Phyllostoma (fi-los′tō-mą), *n.* [NL. (Geoffroy, 1797): see *phyllostomatous.*] A South American genus of phyllostomine bats from which the subfamily and the family each takes its name. *P. hastatum* is one of the largest bats of South America, next in size to *Vampirus spectrum; P. elongatum* is smaller, with a larger nose-leaf.

Phyllostomatidæ (fil″ō-stō-mat′i-dē), *n. pl.* [NL., < *Phyllostoma* (*-stomat-*) + *-idæ.*] A family of tropical and subtropical American bats of the emballonurine series. They have a nose-leaf or other cutaneous appendages of the snout (somewhat as in *Rhinolophidæ* or horseshoe-bats, which are, however, of a different alliance (the vespertilionine)), three phalanges of the middle finger, and large middle upper incisors. The eyes are comparatively large, and there is a distinct tragus (wanting in *Rhinolophidæ*). The family includes the vampire-bats, some of which are true blood-suckers, as the genera *Desmodus* and *Diphylla.* The presence of variously formed appendages of the snout has often caused bats of this group to be confused with the horseshoe-bats; but the presence of a tragus alone is sufficient to distinguish the phyllostomes. Leading genera are *Mormops*, *Vampirus*, *Phyllostoma*, *Glossophaga*, *Stenoderma*, and *Desmodus.* The family is divisible into *Phyllostomatinæ* and *Lobostomatinæ.* Also *Phyllostomidæ.*

phyllotaxis (fil-ō-tak′sis), *n.* [NL.: see *phyllotaxy.*] In *bot.*, the distribution or arrangement of leaves on the stem; also, the laws collectively which govern such distribution. Leaves are distributed so as to economize space and give a good exposure to light; and to accomplish this they are arranged in a variety of ways, which all fall under two principal modes. These are the *verticillate* or *cyclical*, in which there are two or more leaves at the same height of the stem, and the *alternate* or *spiral*, in which the leaves stand singly, one after another. In the verticillate arrangement the leaves form a succession of whorls or circles around the stem, with two, three, four, five, or more in each whorl. In the alternate or spiral arrangement the leaves are distributed singly at different heights of the stem and at equal intervals. The simplest is the two-ranked or distichous arrangement, which prevails in all grasses, in the linden, elm, etc., in which the leaves are disposed alternately on exactly opposite sides of the stem. The second leaf is therefore the furthest possible from the first, and the third is the furthest possible from the second, and consequently is exactly over the first, and so on. They thus form two vertical ranks in which the angular divergence is half the circumference, or 180°. In all cases the angular divergence may be represented by a fraction, in which the numerator designates the number of turns of the spiral that are made in passing from one leaf to the next one that is precisely vertical to it, while the denominator expresses the number of vertical rows thus formed, from which the class of phyllotaxis takes its name, as the tristichous or three-ranked ($\frac{1}{3}$), the pentastichous or five-ranked ($\frac{2}{5}$), the octostichous or eight-ranked ($\frac{3}{8}$), and even as high as a thirteen-ranked ($\frac{5}{13}$) phyllotaxis is not uncommon.

They are of small size, often of metallic colors, and frequently very destructive to vegetation; the larvæ are white and usually linear. *P. vittata* is the wavy-striped flea-beetle of the United States, abundant in vegetable-gardens, where it attacks cabbages and other cruciferous plants. *P. nemorum* of Europe, known as the *turnip flea-beetle*, has similar habits.

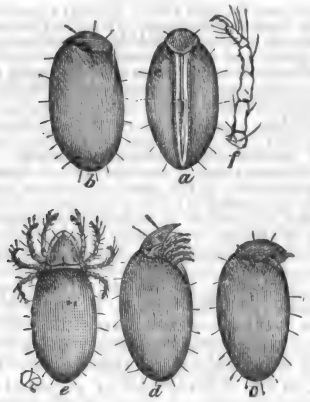
Phylloxera (fil-ok-sē′rą), *n.* [NL. (Fonscolombe, 1834), < Gr. *φύλλον*, leaf, + *ξηρός*, dry.] 1. A genus of plant-lice or homopterous insects of the family *Aphididæ* and subfamily *Chermesinæ*, usually of gall-making habits. The front wings have two discoidal veins, and the antennæ are three-jointed, the third joint being much the longest. The young larvæ have one-jointed tarsi, and all forms are destitute of honey-tubes. It is a somewhat large genus, nearly all of whose species are North American, forming galls on the leaves of the hickory in particular, but also on those of the chestnut, butternut, and oak, as *P. rileyi*, the oak-pest. One species, *P. vastatrix*, is a formidable pest of the European grape (*Vitis vinifera*). See def. 2.

2. [*l. c.*] A member of this genus, especially the species just named, known as the *grape-vine phylloxera* and *vine-pest*, the worst enemy of the European or *vinifera* grape. The fact that a vine-disease which had long existed in southern France was due to this insect was discovered in 1865 by Planchon, who described the insect as *P. vastatrix.* The species



Vine-pest (*Phylloxera vastatrix*).

had been named before (though Planchon's name holds by common consent); for in 1854 Fitch had described an American gall-louse on grape-leaves as *Pemphigus vitifoliæ*, and this was identified with the European root-louse (*Phylloxera vastatrix*) by Riley in 1870. The same discovery was made by European observers in the same year. It is now established that the native country of this phylloxera is North America east of the Rocky Mountains from Canada to the Gulf of Mexico, whence it spread to Europe, and more recently to California, South Africa, New Zealand, and Australia. The insect exists under two distinct forms: the root-form, called *radicicola*, on the roots of the vine, and the gall-form, called *gallicola*, in galls on the leaves of the grape. The galls are transient, being numerous one year and scarce the next. The root-form is like the gall-form at first, but later acquires certain characteristic tubercles. The phylloxera hibernates as a winter egg above or below ground, or as a young larva on the roots. Late in the summer a generation of winged agamic females is produced; these fly abroad and spread the pest. One of the females lays from three to eight delicate eggs in or on the ground or on the under side of the leaf, and from these eggs issue the true males and females, both of which are wingless. These mate, and the female lays the winter egg. The wingless hypogeal female may occasionally lay eggs which bring forth the sexual brood without the intervention of a winged generation, but this is exceptional. The wingless individuals spread from vine to vine, and the winged ones carry the pest from one vineyard to another. The symptoms of the disease above ground are the yellowing of the leaves the second year and the death of the vine the third year. Below ground, little knots are formed on the small fibrous roots the first year; these roots decay the next year, and the lice settle on the main roots. The third year these rot, and then the vine dies. The vines susceptible to this infestation include all the varieties of the *Vitis vinifera*, the wine-grape of Europe and California and the hothouse-grape — the most valuable of the grape family. The French government early offered a reward of 300,000 francs for a satisfactory remedy, but this prize has never been awarded. The most effectual methods of dealing with the phylloxera thus far ascertained are the underground injection of bisulphid of carbon by means of a specially contrived apparatus, the application of a watery solution of sulphocarbonate of potassium, and the grafting of the European vine upon hardy American varieties, as the Taylor, Clinton, and Jacques. See also cuts under *gall-louse*, *oak-pest*, and *vine-pest.*

Thus conceived, physical geography is simply the inorganic geology of to-day; and the inorganic geology of the past is only the integration of a long series of changing physical geographies. Since it has come to be understood that the conditions of the present are an inheritance of the past and that explanation of existing conditions should be included in their description, modern physical geography naturally makes much use of geology. The chief subdivisions of physical geography are: meteorology and climatology, which deal with the atmosphere; thalassography or oceanography, which deals with the oceans; and the study of land forms, for which an older name, orography, is now little used, and for which a newer name, geomorphology, has not found general acceptance. The study of the waters of the lands, formerly named hydrography, is now generally included in the study of the lands. The distribution of plants and animals, formerly treated under physical geography, is now more generally placed under biogeography, of which anthropogeography has received most attention.—**Physical geology,** the study of the geological changes which have taken place on the earth's surface, and of the causes by which these events have been brought about; geology separated, as far as possible, from paleontology, or from any consideration of the order of succession and the nature of organic life upon the globe, and of the classification of the stratified formations in accordance therewith.—**Physical horizon, influx, mineralogy, necessity, optics.** See the nouns.—**Physical influence.** Same as *physical influx*.—**Physical partition,** a partition by which the parts are really separated; real partition: opposed to *ideal partition*.—**Physical perfection, possibility, power.** See the nouns.—**Physical signs,** such features of disease as are directly appreciable by the examiner and are not the expression by the patient of his own feelings, as those elicited by palpation, inspection, auscultation, percussion, etc.—**Physical truth,** the harmony of thought with the phenomena of outward experience.—**Physical whole,** a whole composed of matter and form.=**Syn. 2.** *Corporal*, *Corporeal*, etc. See *bodily*.—3. *Chemical*, etc. See *mechanical*.

physics (fiz'iks), *n.* [Pl. of *physic*, after Gr. *φυσικά*, neut. pl., physics: see *physic.*] Natural philosophy; experimental philosophy; the science of the principles operative in inorganic nature; the science of forces or forms of energy. Before the rise of modern science, *physics* was usually defined as the science of that which is movable, or the science of natural bodies. It was commonly made to include all natural science. At present, vital phenomena are not considered objects of physics, which is divided into *general* and *applied physics*. General physics investigates the general phenomena of inorganic nature, determines their laws, and measures their constants. It embraces four branches—(1) *mechanics* or *dynamics*, the science of force in general, with extensive mathematical developments; (2) the *science of gravitation*, also mainly mathematical; (3) *molecular physics*, the study of the constitution of matter, and of the forces within and between its molecules, including elasticity and heat (an indivisible subject), cohesion, and chemical forces; and (4) the *physics of the ether*, being the study of light or radiation, electricity, and magnetism. Chemistry is for the time being divorced from physics, being chiefly occupied with the description of the formation of different kinds of substances. Applied physics uses the discoveries of general physics, in connection with special observations, in order to explain the phenomena of the universe. Its chief branches are astronomy, geology, and meteorology; to which may be added terrestrial magnetism, mineralogy, and some other subjects.

Also called *physiocratism.*

physiocrat (fiz'i-ō-krat), *n.* [< Gr. *φύσις*, nature, + *κρατεῖν*, rule: see *physiocracy.*] One who advocates the doctrines of physiocracy; specifically, one of a group of French philosophers and political economists, followers of François Quesnay (1694–1774), which rose to prominence in the latter half of the eighteenth century, and maintained that a natural constitution or order exists in society, the violation of which has been the cause of all the evils suffered by man. A fundamental right derived from this constitution or order was held to be freedom of person, of opinion, of property, and of contract or exchange. The physiocrats regarded land or raw materials as the sole source of wealth, leaving out of account the elements of labor and capital, and denying the dogma of the mercantile system that wealth consists in the precious metals. They maintained that, as wealth consisted entirely in the produce of land, all revenue should be raised by a direct tax on land. They advocated complete freedom of trade and the doctrine of laisser-faire. See *physiocracy.*

Phytelephas (fī-tel′ē-fas), *n.* [NL. (Ruiz and Pavon, 1798), so called with reference to the hard albumen, called vegetable ivory; < Gr. *φυτόν*, plant, + *ἐλέφας*, ivory: see *elephant.*] An aberrant genus of palms, type of the tribe *Phytelephantinæ*, and from its singularity long separated as a family *Phytelephanteæ* (*Martius*, 1835). It is unlike all other palms in its numerous stamens, filiform stigmas, and unbranched spadices, and in the elongated petals of its female flower. There are 3 species, all of them natives of tropical America, known from the nut as *ivory-palm.* They are dicœcious trees growing in dense and extensive groves, with a short robust trunk sometimes 6 feet high from a creeping and prostrate base often 20 feet long. They bear a crown of a dozen or more pinnate leaves, reaching 18 or 20 feet in length, resembling those of the cocoanut-palm, and used by the natives in roofing. The male trees are taller, and bear a fleshy and pendulous cylindrical fragrant spadix about 4 feet long, crowded with small flowers between minute bracts, each with about thirty-six stamens, and

exhaling a penetrating odor of almonds. The female tree produces a shorter and erect spadix, six or eight at once, each with six or seven pure-white flowers, which are far the largest among palms, with from five to ten fleshy petals (each from 2 to 3 inches long), three papery triangular sepals, numerous imperfect stamens, and a roundish ovary with from four to nine furrows, carpels, and stigmas, becoming a drupe in fruit. The mass of six or seven drupes from one spadix consolidates into a heavy pendulous globose syncarp, or multiple fruit (from its size known locally as *negro's-head*), covered with hard woody prominences. Each drupe contains about six large seeds; these, when young, are filled with a clear liquid, which is sought by travelers as a drink, and solidifies first into a pulp eagerly eaten by animals, and later into the hardest albumen known, whence its name *ivory-nut.* This again softens in germinating, turning into a milk and pulp, which feeds the young plant until it has grown for a year or more.

were keyboard-instruments more akin to the harp than to the dulcimer. The dulcimer has been known in some form from the earliest historic times. Several attempts were made during the sixteenth and seventeenth centuries to combine a keyboard with it, perhaps the most important being the *pantaleone* of Hebenstreit. The chief esthetic motive to these attempts arose from the fact that the keyboard-instruments then known were nearly or entirely incapable of gradation in the loudness of their tone; hence the new instrument, when invented, was called a *piano e forte*, a *fortepiano*, or a *pianoforte*, because its main peculiarity was that its tone might be made either loud or soft at the player's will. The earliest manufacture of pianofortes of which there is certain record was by Bartolomeo Cristofori of Padua, about 1710. Various improvements have been and are still being made in details, but the essential elements of the mechanism have not been radically changed. These elements are as follows. (*a*) The *frame* or *back* is a framework of metal, with various cross-bars and trusses so planned as to offer a stanch resistance to the tension of the strings. This tension in a modern grand pianoforte amounts to several tons. To the frame are attached on one side or end the *string-plate* and on the other the *wrest-plank*, to the former of which one end of the strings is fastened, while in the latter are set the *tuning-pins*, around which their other end is wound, and by turning which their tension may be adjusted. Frames are sometimes made of wood, but usually of iron, preferably cast in a single piece. (*b*) The *strings* are steel wires of graduated thickness and length, the larger being made heavier by being wound with copper wire. For each of the extreme upper and lower tones only one wire is provided, but for most of the others there are two

or three wires, which are tuned in unison, and placed so that they shall be struck simultaneously by a single hammer. (*c*) The *sounding-board* is a thin plate of selected wood so placed under the strings that it is drawn into sympathetic vibration with them. The sonority and quality of the tones depend much upon its material, form, and attachment. At the side or end next the string-plate there is an opening in the sounding-board for the hammers. (*d*) The *action* comprises the entire system of levers, hammers, etc., by which the player causes the strings to sound. It includes a keyboard (which see) made up of keys or digitals, each of which works on a pivot near its center. When the front end of a key is depressed, the back end is raised, carrying with it a rod called a *jack*, the upper end of which propels a felt-tipped hammer against one or more strings with a blow. At the same instant a *damper* is lifted from the strings so that they can vibrate freely. After the blow is given the hammer falls back against a *check*, while the damper remains lifted until the key is released. Various exceedingly ingenious devices are used to prevent noise, to insure ease, precision, and power, and to provide for extreme rapidity of manipulation. Various mechanical effects are produced by means of pedals, such as the *damper* or *loud pedal*, which lifts the dampers from all the strings at once, so that all the strings sounded shall continue to sound, and other strings shall be drawn into sympathetic vibration until the pedal is released; a *sustaining pedal*, which holds up all the dampers that happen to be raised when it is pressed down, so that selected tones may be prolonged at will; and a *soft pedal*, which either interposes a strip of thin felt between the hammers and the strings, or diminishes the distance from which the hammers strike, or moves them to one side, that they may strike only one instead of two or three strings, so that a soft tone shall be produced. The compass of the keyboard varies from five to seven and a half octaves. Great care is taken that the hammers shall strike the strings at such a point as to bring out their desirable harmonies, and suppress the others. (*e*) The *case* is a wooden box in which the whole instrument is contained. Its form varies according to the variety of the pianoforte. A *grand piano*, the largest form of which is called a *concert grand*, is harp-shaped, like the harpsichord, and has the strings strung horizontally at right angles to the keyboard. A *square piano*, until lately the commonest form for private use, is rectangular, like the clavichord, and has the strings strung horizontally, parallel with the keyboard. An *upright* or *cabinet piano* is like a square set up on edge, and has the strings strung vertically behind the keyboard. In both these varieties the case is often made of precious woods elaborately carved and inlaid. The importance of the pianoforte rests upon its powerful and finely graduated tone, its convenience for the production of concerted music, and its universal popularity. Its wide-spread use brings into prominence, however, the disadvantages of a percussive tone, which cannot be sustained or varied after the initial stroke, of an ease of manipulation which invites slovenly and vulgar use, and of a temperament which, with the common neglect of frequent tuning, often hopelessly corrupts the player's musical ear. The technique of the pianoforte has developed gradually out of that of the harpsichord and clavichord. Abbreviated *pf.*—**Oblique pianoforte.** See *oblique*.—**Pianoforte-player's cramp,** an occupation-neurosis, allied to writer's cramp, developing in pianoforte-players.—**Sostinente pianoforte,** a name given to various forms of the pianoforte constructed with a view to sustain the full tone like an organ. It consists of a ground-theme or air called the *urlar*, followed by several variations, generally three or four, the whole concluding with a quick movement called the *creanduidh*. Pibrochs usually increase in difficulty from the beginning to the end, and are profusely ornamented with grace-notes called *warblers*. They are generally intended to excite a martial spirit. They also often constitute a kind of program-music, intended to represent the various phases of a battle—the march, the attack, the conflict, the flight, the pursuit, and the lament for the fallen. The names they bear are often derived from historical or legendary events, as "The Raid of Kilchrist," attributed to the piper of Macdonald of Glengarry, and supposed to have been composed in 1603. The term is sometimes used figuratively by poets to denote the bagpipe itself.

pica4 (pī′kä), *n.* [So called with ref. to the black-letter type in which the pica or ordinal was printed: see *pica*3.] A size of printing-type, about 6 lines to the inch, intermediate between the sizes English (larger) and small-pica (smaller). It is equal to 12 points in the new system of sizes. (See *point*1, 14 (*b*).) The sizes of type respectively called 2-, 3-, 4-, 5-, and 6-line pica have bodies that are equal to 2, 3, 4, 5, and 6 lines of pica. Leads are described by their numerical relation to the pica body, as 6-to-pica or 10-to-pica, according as 6 or 10 set together make a line of pica.

This is Pica Type.

Double pica, in England, a size of type equal to 2 lines of small-pica.—**Double small-pica,** in *printing*, a size of type giving about 3½ lines to the inch. In Great Britain this size is known as *double pica*.—**Two-line pica,** a size of type of about 3 lines to the inch, equal to 2 lines of pica, or to 24 points in the new system of sizes.

The horse of the picador is often disemboweled by the bull; the man has armor for the legs, as much to keep them from being crushed by the weight of the horse falling on them as to protect them against the bull.

The light darts of the *picador* . . . sting, but do not wound. *G. W. Curtis*, Harper's Mag., LXXVI. 637.

Picæ (pī′sē), *n. pl.* [NL., pl. of *Pica:* see *Pica*1.] In the Linnean system of classification, the second order of birds, more fully called *Aves picæ*. It consisted of the genera *Psittacus, Ramphastos, Buceros, Buphaga, Crotophaga, Corvus, Coracias, Oriolus, Gracula, Paradisea, Trogon, Bucco, Cuculus, Yunx* (*Iynx*), *Picus, Sitta, Todus, Alcedo, Merops, Upupa, Certhia*, and *Trochilus*. Though thus a heterogeneous and artificial group, it corresponds in the main with the modern order *Picariæ*, of which it is the prototype. Elimination of the passerine forms (namely, *Corvus, Oriolus, Gracula, Paradisea, Sitta*, and *Certhia*) would leave it very nearly the same as *Picariæ*.

the beginning of the seventeenth century, of which "Guzman de Alfarache" was a type.

The rise of the taste for *picaresque* literature in Spain towards the close of the 16th century was fatal to the writers of pastoral. *Encyc. Brit.*, XVIII. 346.

Picariæ (pī-kā′ri-ē), *n. pl.* [NL., fem. pl. of **picarius*, < L. *picus*, a woodpecker: see *Picus*.] In Nitzsch's system of classification, as edited by Burmeister in 1840, an order of birds, instituted for the reception of the *Macrochires*, *Cuculinæ*, *Picinæ*, *Psittacinæ*, and *Amphibolæ* of his earlier arrangement, with the addition of the *Caprimulginæ*, *Todidæ*, and *Lipoglossæ* (the last consisting of the genera *Buceros*, *Upupa*, and *Alcedo*). With various modifications, and especially with the exclusion of the *Psittaci*, the term continues in general use by ornithologists as the name of a group of non-passerine non-raptorial land-birds; but it is so heterogeneous that no diagnostic characters can be assigned, and the tendency now is to drop the term and elevate several of the groups of genera which it formerly covered to ordinal or subordinal rank, under the names *Macrochires*, *Coccyges*, and *Piciformes*, or their equivalents.

Picea (pī′sē-ä), *n.* [NL. (Link, 1827), < L. *picea*, the pitch-pine, or perhaps the spruce or the fir (cf. Gr. *πεύκη*, the fir), < *pix* (*pic-*), pitch: see *pitch*.] A genus of trees, of the family *Pinaceæ*, tribe *Abieteæ*, including the spruce. It is characterized by the evergreen four-sided leaves jointed to the persistent petiole-base, staminate flowers solitary in the axils of the upper leaves, and reflexed cones with persistent scales, hanging near the end of the branches. Great confusion regarding the spruce and fir existed among the Greeks and Romans, and later among moderns; many authors (following Don, 1838) long wrote *Picea* for the fir, *Abies* for the spruce; Asa Gray and others (following Jussieu, 1789) united both under *Abies*; present usage adopts (since Bentham and Hooker, 1880) *Picea* for the spruce, *Abies* for the fir. *Picea* includes about 14 species, natives of north temperate and subarctic regions. They bear long and narrow spirally scattered leaves spreading in all directions, and long cones with double thin-margined scales each with two winged seeds. See *spruce* and *king-pine*, and compare *fir* and *Burgundy pitch*, under *pitch*[2].

Picidæ (pis′i-dē), *n. pl.* [NL., < *Picus* + *-idæ*.] A large family of scansorial zygodactyl picarian birds, named from the genus *Picus*, characterized by the habit of picking the wood of trees

both to procure food and to construct nesting-places; the woodpeckers. (*a*) In a broad sense, a family including the piculets and wrynecks, which have soft tail-feathers not used in climbing, and divided into *Picinæ*, *Picumninæ*, and *Iynginæ*. See cuts under *Picumnus*, *Picus*, and *wryneck*. (*b*) By exclusion of the last two as respectively types of different families, the woodpeckers proper, which have stiff acuminate tail-feathers used in climbing, being pressed against the tree, and forming with the feet a tripod of support. The tail consists always of twelve rectrices, but the next to the outer pair are very small and concealed, so that there appear to be only ten. The wing is more or less pointed, with ten primaries, of which the first is short or spurious; the coverts are short, as in passerine birds. The feet are four-toed and zygodactyl (excepting in the genus *Picoides*). The arrangement of the flexor tendons of the toes is antiopelmous, the oil-gland is tufted, the carotid is single, cæca are wanting, and the manubrium of the breast-bone is bifurcate. The principal peculiarities are found in the skull, beak, and tongue. The palatal structure is unique and of the type called by Parker *saurognathous*, and the whole skull is remarkably solid and firm. The beak is eminently fitted, like a gouge or chisel, for boring into wood. In some of the less typical *Picidæ* this instrument is a little curved, acute, and not ridged on the sides; in most woodpeckers, however, it is perfectly straight, very hard, truncated chisel-wise (perpendicularly) at the end, and beveled and strengthened with ridges on the sides. Except in a few genera (as *Sphyropicus*), the tongue is lumbriciform or cylindrical, barbed at the end, and capable of great extension; it is used as a spear to capture insects. The horns of the hyoid bone are very highly developed, as a rule, curling up over the back of the head, even as far as the orbital or nasal cavities, and the salivary glands are very large. The species are numerous (upward of 300), placed in many modern genera, inhabiting nearly all parts of the world. They are chiefly insectivorous, but also frugivorous to some extent, nest in holes which they excavate with the bill, and lay crystal-white eggs. They are not regularly migratory, and not musical. Besides their vocal cries, they make a loud rattling noise by tapping trees. See cuts under *Campophilus*, *Centurus*, *Dryocopus*, *flicker*, *Melanerpes*, *pair-toed*, *Picus*, *pileated*, *pitahaya*, *popinjay*, *sapsucker*, *woodpecker*, and *Xenopicus*.

piciform (pis′i-fôrm), *a.* [< NL. *piciformis*, < L. *picus*, a woodpecker, + *forma*, form.] Having the form or structure of a woodpecker; related to the woodpeckers; picoideous; specifically, of or pertaining to the *Piciformes*.

Piciformes (pis-i-fôr′mēz), *n. pl.* [NL., pl. of *piciformis*: see *piciform*.] 1. In Garrod's classification, a superfamily of anomalogonatous picarian birds, having a tufted oil-gland, one carotid, and no cæca, including the *Picidæ* and some related families: contrasted with *Cypseliformes*.—2. In Coues's system (1884), the woodpeckers alone as a suborder of *Picariæ*, composed of the three families *Picidæ*, *Picumnidæ*, and *Iyngidæ*.

Picinæ (pi-sī′nē), *n. pl.* [NL., < *Picus* + *-inæ*.] In *ornith.*: (*a*†) In Nitzsch's classification (1829), a superfamily of birds, equivalent to the *Dendrocolaptæ* of Merrem. (*b*) A subfamily of *Picidæ* (*a*), made by elimination of the *Picumninæ* and *Iynginæ*: same as *Picidæ* (*b*). (*c*) A subfamily of *Picidæ* (*b*), containing the most typical woodpeckers, which have the bill perfectly straight, ridged and beveled on the sides, and truncate at the end, and the tongue usually extensile.

★ **II.** *n.* One of the *Picidæ*.

the middle to receive a handle or helve. The tips of the pick are usually sharpened to a point by a square taper; sometimes, however, to a chisel-edge. The tapering extremities of the pick possess the property of the wedge, so that this tool is really hammer and wedge in one. Its form allows it also to be advantageously used as a bent lever. The pick is known in England by the names *pike*, *mandrel*, *slitter*, *mattock*, and *hack*; the last two, however, belong properly to forms of the pick with only one point and that ending in a chisel-edge. pig[1] (pig), *n.* [Also dial. *peg*; early mod. E. *pigge*; < ME. *pigge*, *pygge* = D. *bigge*, *big* = LG. *bigge*, a pig; origin obscure. An AS. **pecg* is mentioned as occurring "in a charter of Swinford copied into the Liber Albus at Wells" (Skeat, on authority of Earle); but this is doubtful; an AS. **pecg* would hardly produce the E. form *pig*. Whether the word is related to LG. *bigge*, a little child, = Dan. *pige* = Sw. *piga* = Icel. *pīka*, a girl, is doubtful.] 1. A hog; a swine; especially, a porker, or young swine of either sex, the old male being called *boar*, the old female *sow*. It is sometimes used in composition to designate some animal likened to a pig: as, a guinea-*pig*. See *hog*, *Suidæ*.

Together with the cottage . . . what was of much more importance, a fine litter of new-farrowed *pigs* no less than nine in number perished. *Lamb*, Roast Pig.

2. The flesh of swine; pork.

Now *pig* it is a meat, and a meat that is nourishing and may be longed for, and so consequently eaten; it may be eaten; very exceedingly well eaten.

3. An oblong mass of metal that has been run while still molten into a mold excavated in sand; specifically, iron from the blast-furnace run into molds excavated in sand. The molds are a series of parallel trenches connected by a channel running at right angles to them. The iron thus cools in the form of semi-cylindrical bars, or pigs, united at one end by another bar called the *sow*: so called from a coarse comparison with a litter of pigs suckling.

[We found] many barres of Iron, two *pigs* of Lead, foure Fowlers, Iron shot, and such like heauie things throwne here and there.
Quoted in *Capt. John Smith's* Works, I. 104.

Sometimes a *pig* will solidify partly as white iron partly as grey, the crystallization having commenced in patches, but not having spread throughout the whole mass before it solidified; such iron is known as mottled *pig*.
Encyc. Brit., XIII. 284.

Dickens, Pickwick, xxxii.

Please the pigs, if circumstances permit: a trivial rustic substitute for *please God* or *if it please Providence*. *Pigs* is here apparently a mere alliterative caprice; it has been variously regarded as an altered form of *pix*, *pyx*, the box which held the host; or of *pixies*, fairies; or of the "Saxon *piga*, a virgin" (as if meaning the Virgin Mary). These conjectures are all absurd. As to the last, no "Saxon *piga*" exists; the entry "*piga*, puellula," in Somner, Lye, etc., is an error.

I'll have one of the wigs to carry into the country with me, and [if (it)] *please the pigs*. *T. Brown*, Works, ii. 198.

Sussex pig, a vessel in the form of a pig, made at the Bellevue or other Sussex pottery. When empty it stands upon the four feet, but when in use it stands upright, its head is lifted off to allow of its being filled, and it serves as a drinking-cup. The jest of being ordered to drink a "hogshead" of beer in response to a toast, or the like, refers to the emptying of such a cup. See *Sussex rustic ware*, under *ware*.—**To bring one's pigs to a pretty market,** to make a very bad bargain, or to manage anything in a very bad way.

For the form, cf. *widgeon*. The native (AS.) word for 'pigeon' is *dove*: see *dove*[1].] 1. Any bird of the family *Columbidæ* (which see for technical characters); a dove. The species are several hundred in number, and are found in nearly all parts of the world. Many kinds are distinguished by qualifying terms, as *fruit-pigeon*, *ground-pigeon*, *passenger-pigeon*, *nutmeg-pigeon*, *rock-pigeon*, and any of them may be called *dove*, as *stock-dove*, *rock-dove*, *ring-dove*, *turtle-dove*, *wood-dove*. (See the compound names, and *dove*[1].) Few species are commonly seen in confinement, except in very extensive aviaries, one of the commonest being the ring-dove; but the rock-pigeon or rock-dove, *Columba livia*, is everywhere thoroughly domesticated, and perhaps all the artificial varieties have been produced by careful breeding from this one. Fancy pigeons have naturally received many fanciful names of their breeds, strains, and endless color-variations. Some of these names are—(*a*) from localities, actual or alleged, as Antwerps, barbs (from Barbary), Brunswicks, Burmeses, Damascenes, Florentines, Lahores, Orientals, Swabians; (*b*) from resemblance to other birds, as magpies, owls, starlings, swallows, swifts; (*c*) from characteristic actions, as carriers, croppers, dragoons, homers, pouters, rollers, shakers, trumpeters, tumblers; (*d*) from peculiarities of size, shape, or color, as capuchins, fantails (see cut under *fantail*), fire-pigeons, frills or frill-backs, helmets, hyacinths, ice-pigeons, jacobins (see cut under *jacobin*), nuns, porcelains, priests, runts, shields, turbits. Some names, like *archangel*, *mawmet*, and *victoria*, are unclassifiable, and others are quite peculiar to fanciers' nomenclature, as *blondinette*, *silverette*, and *turbitteen*. Young pigeons are known as *squabs* and *squealers*. The name *pigeon* is also used, with a qualifying word, to designate some bird like or likened to a pigeon, as *prairie-pigeon*, *sea-pigeon*, etc.

Any substance that is or can be used by painters to impart color to bodies; technically, a dry substance, usually in the form of a powder or in lumps so lightly held together as to be easily pulverized, which after it has been mixed with a liquid medium can be applied by painters to surfaces to be colored. *Pigment* is properly restricted to the dry coloring matter which when mixed with a vehicle becomes a *paint*; but the two words are commonly used without discrimination. (See *paint*.) In oil-painting, the pigments are ground or triturated to render them smooth, usually in poppy- or nut-oil, since these dry best and do not deaden the colors.

If you will allow me, Pyrophilus, for the avoiding of ambiguity, to employ the word *pigments* to signify such prepared materials (as cochineal, vermilion, orpiment) as painters, dyers, and other artificers make use of to impart or imitate particular colours. *Boyle*, Works, II. 48.

2. In *biol.*, organic coloring matter; any organized substance whose presence in the tissues of animals and plants colors them. *Pigment* is the generic or indifferent term, most kinds of pigment having specific names. Coloring matter of one kind or another is almost universal in animals and plants, comparatively few of which are colorless. Pigments are very generally distributed in the integument and its appendages, as the skin, and especially the fur, feathers, scales, etc., of animals, and the leaves and other soft parts of plants. The dark color of the negro's skin is due to the abundance of pigment in the epidermis. The black appearance of the pupil of the eye is due to the heavy pigmentation of the choroid, and various colors of the iris depend upon specific pigments. Such coloring matters are often accumulated in special cells which expand and contract, producing the "shot" or play of color of the chameleon, dolphin, cuttle-fish, and other animals. In many low animals and plants the color of the pigment is characteristic of genera, families, or even higher groups, as among infusorians, algals, etc. See cut under *cell*.

(*b*) (1) A sharp-pointed weapon consisting of a long shaft or handle with an iron head. It has been in use from ancient times, but the word dates apparently from the fifteenth century. About that period, and for some time later, it was the arm of a large part of the infantry, and was from 15 to 20 feet long. It continued in use, although reduced in length, throughout the seventeenth century, and was replaced by the bayonet as the latter was improved. It was retained in the British army until a very late date as a mere ensign of rank. (See *half-pike* and *spontoon*.) The pike has always been the arm of hastily levied and unequipped soldiers; thousands were used in the French revolution. Such pikes have usually a round conical head, a mere ferrule of thin iron bent into that form, but long, sharp-pointed, and formidable. The pike of regular warfare had sometimes a round, sometimes a flat or spear-like head.

A pointed stake; specifically, in *arch.* and *engin.*, a beam, heavy, generally of timber, often the roughly trimmed trunk of a tree, pointed or not at the end and driven into the soil for the support of some superstructure or to form part of a wall, as of a coffer-dam or quay. For permanent works piles are driven in loose or uncertain strata in rows, leaving a space a few feet in width between them, and upon the heads of the piles the foundations of the superstructure are erected. In temporary constructions they are driven close together in single or double rows, so as to inclose a space of water and form a coffer-dam, from which the water is subsequently pumped out, and thus a dry space is obtained for laying the foundation of piers, etc., in bridges and other similar works. Iron piles are used for wharf-walls and other purposes; they are hollow or tubular within, and are cast in various forms. See cuts under *lake-dwelling*, *pile-driver*, and *pilework*.

False pile, an additional length given to a pile after driving. *E. H. Knight.*—**Gaged piles**, large piles placed at regular distances apart, with horizontal beams called *runners* fitted to each side of them by notching, and secured by bolts. They form a guide for the filling-piles, which are driven between the runners, filling up the spaces between them.—**Hollow pile**, a large wrought- or cast-iron cylinder sunk in sandy strata by digging away or forcing out the sand from the inside. Sections of cylinder are added above, as may be necessary, and secured by flanges and bolts.—**Hydraulic pile**, a pile sunk in sand by means of a water-jet. Two methods are followed. In one, a hollow iron pile is set upright in the sand in the position it is to occupy, while a powerful stream of water is forced into the pile and escapes through a hole at the point of the tube, forcing up the sand, so that the tube rapidly sinks. In the other method, solid wooden piles are sunk in the same manner, the jet being delivered at the foot of the pile by means of an iron pipe let down beside the pile and afterward withdrawn. On stopping the water-jet the sand quickly settles around the pile and holds it firmly in position.—**Pneumatic pile**. See *pneumatic*. (See also *screw-pile*, *sheet-pile*.)

Shak., Hen. V., i. 2. 195.

=Syn. *Pillage, Plunder, Booty, Spoil, Prey.* These words denote that which is violently got or carried off; all except *prey* suggest a considerable amount seized. *Pillage* also denotes the act; the others only the thing or things taken. *Pillage* and *spoil* especially suggest the great loss to the owners, completely stripping or despoiling them of their property; *plunder* suggests the quantity and value of that which is taken: as, loaded with *plunder; booty* is primarily the spoils of war, but also of a raid or combined action, as of pirates, brigands, or burglars; *spoil* is the only one of these words that is used in the plural, except, rarely, *prey*. *Prey* now seems figurative or archaic when not applied to the objects of pursuit by animals: as, the mouse falls a ready *prey* to both beasts and birds; hence, when applied to that which is pursued or taken by man, it expresses condemnation of the act.

Knotted pillar. See *knotted*.—**Pillar and breast**, a common method of mining coal, in which the breasts or working-places are rectangular rooms, usually five or ten times as long as they are broad, and opened on the upper side of the gangway, or main haulage-road, or level driven on the strike of the coal. The breasts are made of various widths, usually from five to twelve yards, according to the character of the roof, but not so wide that the roof will not sustain itself. These breasts or rooms are separated by pillars of coal, broken only by cross-headings where these are needed for ventilation. The pillars are sometimes left so narrow that it is not expected they will permanently support the roof of the mine; in such cases the object of the method is to get as much coal as possible in the shortest time and at the least expense. If more economy of coal is considered desirable, the pillars are left wider, and, after the breasts are entirely worked out, are "robbed"—that is, are cut away until all the coal has been obtained from them which can be removed without too great danger to the miners. This method of mining is also called *post and stall*, *pillar and stall*, *pillar and room*, *stoop and room*, *board and pillar*, etc. See *long-wall*.—**Pillar dollar**, a silver coin of Spain (so called from its figure of the Pillars of Hercules), coined especially for use in the former Spanish colonies in America. The application of the term is generally limited to an ornamental spire-shaped structure, standing on parapets, angles, and buttresses, and often adorned with rich and varied devices. Pinnacles are very numerous in the fully developed medieval style; their shafts are sometimes formed into niches, and are sometimes paneled or quite plain; in examples of late date, every one of the sides generally terminates in a gablet. The tops are often crocketed, and have finials at the apex. Pinnacles are most often square in plan, but are sometimes octagonal, hexagonal, or pentagonal. See also cut under *crocket*.

2. One of the tubes of metal or of wood from which the tones of an organ are produced; an organ-pipe. Such pipes are either flue- or reed-pipes. The tone is produced in flue-pipes by the fluctuations of a compact focused stream of air impinging upon a sharp edge or lip, and in reed-pipes by the vibration of a metal tongue hung in a stream of air. Metal pipes of either class are usually circular in section, while wooden pipes are usually square or triangular. (*a*) Flue-pipes consist of a *body* and a *foot*, the division between which is marked by an opening on one side of the pipe, called the *mouth*. The upper and lower edges of the mouth are called *lips*, and its sides are often shielded by *ears*. Opposite the lower lip a horizontal shelf, called the *language* or *languid*, is inserted so as nearly to separate the pipe into two distinct cavities. Between this shelf and the lower lip is a narrow slit called the *flue* or *wind-way*, through which the stream of air is directed against the upper lip. The quality of the tone depends upon the general shape of the pipe, and especially upon a delicate adjustment of the language and lips called *voicing*. The pitch of the tone depends upon the length of the vibrating column of air within the body. The upper end of the pipe may be open, or may be closed with a plug; an open pipe gives a tone an octave higher than a stopped pipe of the same length. Tuning is effected by altering the effective length of the air-column in various ways; and the adjustable metal flaps or tongues placed at the top of the pipe for this purpose are called *tuners*. The lower end of the pipe is open for the admission of air from the wind-chest. (*b*) Reed-pipes consist of a *tube* or *body* and a *mouthpiece*, the only communication between which is through a short metallic tube called the *shallot*, or reed proper. The oblong opening into the lower part of the shallot is covered or filled by a thin, elastic piece of brass called the *tongue*, or sometimes the *reed*. When the tongue covers the opening, the reed is *striking*; when it merely fills the opening, the reed is *free*. The quality and power of the tone depend largely upon the material and shape of the body, which serves almost exclusively as a resonance-chamber. The pitch of the tone depends upon the vibrating length of the tongue. Tuning is effected by adjusting a wire spring of peculiar shape so as to lengthen or shorten the part of the tongue left free to vibrate: this spring is called the *tuning-wire*. In the organ, pipes of the same variety are arranged in sets called *stops* or *registers*, containing at least one pipe for each key of the keyboard. (See *stop* and *organ*[1].) The breadth and sonority of a pipe's tone are much influenced by its *scale*—that is, by the general ratio between its width or diameter and its length; broad, bulky pipes giving broad, diapason-like tones, and narrow pipes giving thin, incisive tones. The proportions between the several dimensions of the different kinds of pipes are regulated by somewhat intricate mathematical formulæ. The number of pipes in an organ is approximately equal to the product of the number of keys in the keyboards and the number of stops. The organ at Weingarten is said at one time to have contained 6,666 pipes. The largest pipe in an organ is the deepest one belonging to a 16- or 32-feet open stop of the pedal organ; such a pipe is usually of wood, and is about 16 or 32 feet long. The smallest pipe is the highest one belonging to one of the mixture-stops, and is usually smaller than a common lead-pencil. Pipes are made either of wood or of metal. The metal most in use for this purpose is called *pipe-metal* or *organ-metal*, and is an alloy of tin and lead. Pure tin, zinc, and lead have also been used, and a great variety of their alloys. When a pipe is sounded, it is said to *speak*. When it fails to speak properly, or speaks when not wanted, it is said to *cipher*.

3. Any hollow or tubular thing or part: as, the *pipe* of a key.—**4.** A tube of metal, wood, or earthenware serving for various uses, as in the conveyance of water, gas, steam, or smoke: as, a gas-*pipe*; a stove-*pipe*.—**5.** A large round cell in a bee-hive, used by the queen-bee. *Halliwell*.—**6.** A tube of clay or other material with a bowl at one end, used for smoking tobacco, opium, or other narcotic or medicinal substance. See *chibouk, hooka, hubble-bubble, narghile*.

8. A wine-measure, usually containing about 105 imperial gallons, or 126 wine-gallons. Two pipes, or 210 imperial gallons, make a tun. But in practice the size of the pipe varies according to the kind of wine it contains. Thus, a pipe of port contains nearly 138 wine-gallons; of sherry, 130; of Madeira, 110; and of Lisbon, 140. Sometimes confounded with *butt* (which see).

The pint you brought me was the best
That ever came from *pipe*.

pipe-die (pīp'dī), *n.* 1. In a press for molding earthenware pipes, the ring-shaped die which shapes the exterior surface of the pipe. A piece called the *core* is supported in such manner that one of its extremities protrudes outwardly into, and is held concentrically within, the pipe-die. This forms an annular opening, through which the plastic clay is forced by heavy pressure, to give it the form of a tube. The inside of the socket on the end of the pipe is shaped by what is called a *lower die*, and the outside of the socket is formed by a device called the *ring*, which is interposed between the outside die and a flange on the lower die.

2. A female screw or nut of hardened and tempered steel used for cutting male threads on the ends of metal pipes. The threads of the die have grooves cut across them parallel with the axis on which the die rotates. In cutting pipe-threads, these grooves afford clearance for escape of the metal cuttings, which would otherwise accumulate in the threads of the die and prevent a clean, uniform cut.

3. Any one of the radially arranged and simultaneously adjustable screw cutting-tools which in some kinds of pipe die-stocks have their inner ends formed like chasers for cutting male screws. (See *chaser*[2].) A right-hand die is one that cuts a right-handed screw-thread. One which cuts a left-handed thread is a left-hand die. See *screw-thread*. Also called *outside die*.

pipe-line (pīp'līn), *n.* A conduit of iron pipe, chiefly laid under ground, through which oil is forced by pumping to transport it from an oil-region to storage-tanks at a general market or refinery. The method has been put in operation in the United States and elsewhere, as a substitute for other means of transportation, and carried out with all the refinements of modern pumping-machinery, the result being an enormous reduction in the cost of transportation and in the cost of petroleum products to consumers. The conduits are constructed of lap-welded iron pipes, with pumping-stations at intervals of varying lengths, according as the grade is ascending or descending, the average being about 30 miles. The diameters of the pipes are adapted to the needs of the various lines, 6 inches being the size used on most trunk-lines, and two or more pipes being employed when greater capacity is required. The longest existing trunk-line is that connecting the Pennsylvania oil region in opposite directions with New York and Chicago. This and other trunk-lines, and lines leading from wells to pumping-stations, etc., make up an aggregate extent of many thousand miles. The pipes are liable to obstruction from deposits of paraffin and foreign matters. Such accumulations are removed by driving a sort of piston (called by the workmen a "go-devil") through the pipes, from station to station, by the pressure of the liquid column behind it.
